MEDICAL AND SURGICAL REPORTER:

A WEEKLY JOURNAL.

(ESTABLISHED IN 1858, BY S. W. BUTLER, M.D.)

EDITED BY

D. G. BRINTON, M.D.

AND

JOSEPH F. EDWARDS, M.D.

JANUARY—JULY, 1883.

VOL. XLVIII.

PHILADLPHIA:

NO. 115 SOUTH SEVENTH STREET.

1883.

CONTRIBUTORS.

ADAMS, J. S., 173.
ALBERT, E., Clinic, 204.
ALLEN, H., 573.
ASHHURST, J. JR., Clinic, 64, 127.
ATLEE, W. F., 402.
AULDE, JOHN, 340.
AYLER, JOHN W., 110.

BAILLARGER, M., Clinic, 685.
BARKER, M. P., 2, 29.
BASHORE, D. W., 193.
BATES, JAS., 446.
BAUER, JOS. L., Clinic, 95, 398.
BEATES, H. JR., 570.
BEAVER, DAN L. B. D., 116.
BELLAMY, B. C., 446.
BERGMANN, PROF., 82.
BERNARDY, E. P., 60.
BLACKWELL, E. T., 166, 368, 671.
BLOSE, J. U., 193.
BRISAC-DREYFUS, M., 281.
BROWN, I., 193.
BURRITT, H. L. W., 258, 701.

CRAIG, A., 537.
CARRELL, W. C., 27.
CLARIDGE, W. R., 655.
CROTHERS, T. D., 88, 169, 283.

DALAND, J., 701.
DANA, C. L., 146.
DELAFIELD, FRANCIS, 289.
DEVELIN, E., Report, 344, 484.
DRAPER, W. H., PROF., Clinic, 150, 260, 346, 402, 455, 544.
Du CAZAL, M., PROF., 365.

EDWARDS, W. A., 230, 335, 400, 595.
ENGEL, H., Report, 204.
ESKRIDGE, J. T., 565.

FORWOOD, W. S., 705.
FULLER, C., 362.

GIBB, JOSEPH, 681.
GILLIFORD, R. H., 627.
GLEASON, A. A., Report, 685.
GOODELL, WM., Clinic, 231.
GRISWOLD, E., 110.

HAMILTON, GEO., 229, 427, 461, 486, 649.
HAMILTON, H., 540.
HARWOOD, W. H., 53.
HAY, THOS., 81, 399.

INDEX.

- Abdominal section; resume of twenty-five cases of, 68; walls, rupture of, 274; presentation, 277; aneurism rupturing into psoas muscle, 321; section, cases of, 384; cystic tumor, 402; pulsation, 549.
- Abdominalorrhaphy cysto, 443.
- Abdomen, congenital sarcoma, 696.
- Abdominal, sanguineous cysts, 701.
- Abnormal ocular condition through, 560.
- Abortive treatment, of variola, 655; of infectious diseases, 690.
- Abscess, and stricture of œsophagus, 145; discharging at, 378; in nasal chambers, 573; at base of brain, 629; hepatic, 694.
- Abscesses; perisplenic, 72; of neck, without cicatrices, 303; hepatic, indicative of, 304.
- Abstraction of blood from right heart, relieving intense pulmonary congestion, 108.
- Academy of Medicine of New York; officers of, 223; and the new code, 521.
- Access of melancholy, appearing at, 685.
- Accidents produced by lumbrici, 496.
- Acid; pyrogallie in phagedena, 191; in eczema, 552; salicylic and acute rheumatism, 193; boracic powder, 194; boracic ointment, 305; phenic in, 330; uric, synthesis of, 350; salicylic in, 355, 356; salicylic, effect of, 379; carbolic injections in hydrocele and cystic tumors, 406; sulphurous in, 463.
- Acid; picric, test for, 669; carbolic, in, 670.
- Acne, rosacea, treatment of, 276.
- Acne; sulphur preparations in, 654.
- Aconite and belladonna in erysipelas, 80.
- Acquitted, Dr. Forbes, 327.
- Act, anatomy, new, 216.
- Action of quinine to hasten the, 82; of thymol on circulation, 191.
- Acute articular rheumatism, 10; yellow atrophy, chemistry of, 50; pneumonia, an infectious disease, 50; cardiac disease, complicated by, 108; rheumatism, salicylic acid and, 193; catarrh of nose, 218; urethritis, 255; rheumatism, 259; rheumatism, treatment of, 411; tonsillitis sodium, bicarbonate in, 305; anæmia, transfusion of saline solutions in, 465; yellow atrophy of liver, 492; rheumatism, prescription for, 500; articular rheumatism in, 668.
- Addiction, opium, 474.
- Address of Dr. Varian, 505; in obstetrics, 513.
- Adherent placenta, 407.
- Adonis vernalis, 305.
- Advertising in lay journals, 363.
- Adulterations of oil of gaultheria, 25.
- Air; ozonized as a hypnotic, 26.
- Air, rarefied action of, 377.
- Albumen; picric acid test for, 669.
- Albuminuria, chloral in, 189.
- Albuminuric retinitis of pregnancy, 589.
- Alcoholism; influence of, 664.
- Alcohol, as a beverage and medicine, 141; influence of, on Bright's disease, 166; mortality, referable to, 190, 273; in scarlatina, 303; in typhoid fever, 624.
- Alcoholism; cause of sterility, 612.
- Alimentation; artificial infant, 540.
- Allied features and statistics of diphtheria, 119.
- Alkaline salts and urea, excretion of, in convalescence, 25.
- Alms-house hospital, 111.
- Alopecia, premature, 698.
- Alterative tonic, 445.
- American, wet nurses, 28; medical editors, association of, 363; medical association, 563.
- Amputation, cerebral atrophy consecutive to, 696.
- Amputation of arm, in a woman aged 82, 353; coat sleeve, 614; subperiosteal at hip-joint, 614.
- Amyloid degeneration of the liver, 34.
- Anæsthesia, by rapid breathing, 23; by caustic applications, 639.
- Anæsthetic properties of ether, 563.
- Anæsthetics during labor, 635.
- Analyses of foods, 377.
- Anal irritation; pear-grit cause of, 594.
- Anatomical specimens in offices, 111.
- Anatomy? shall physicians learn, 46; act, new, 216.
- Anchylolysis of elbow-joint, 484.
- Ancient Rome and the Campagna, 610.
- Aneurism of, 589, 631, 632; popliteal, radical cure of, 34; abdominal, rupturing into, 321; popliteal cured by, 344; cerebral, curability of, 498; axillary, 700; of anterior communicating artery, 700.
- Angina pectoris, 666; nitro-compounds in, 663.
- Aniline dyes, injurious effects on health of, 548.
- Animal substances, presence of mercury in, 639.
- Animation, prolonged, suspended, 693.
- Annual Commencement of Woman's Medical College, 335.
- Anomaly in hearing, 702.
- Anomaly of conjunctiva, 294.
- Ano, fistula in, 302.
- Another remarkable family, 53.
- Antiseptic inhalations in phthisis, 669.
- Antiseptics in phthisis, 663.
- Anteflexion and subinvolution in, 339.
- Anterior wall, ulcer of stomach in, 153.
- Anti-quinine treatment of intermittent fever, 697.
- Anti-vaccination agitation in, 307.
- Antiseptic, meteorological, 18; non, dressings, 25; naphthalin an, 276; glacialine, 303; treatment in puerperal diseases, 309; method, 478; prolonged baths, 548.
- Antiseptics, 71; on micro-organisms, action of, 478.
- Antithermic treatment by cold baths, 621.
- Anus, iodoform a local application in fissure of, 399.
- Aorta, aneurism of, 631.
- Aortic incompetence, pulsation of spleen in, 244; orifice, ossification at, 375.
- Apoplexy, atmospheric pressure and, 190; treatment of, 470.
- Arsenic in diabetes, 329; bromide of, 357.
- Arsenical paralysis, 206; paralysis, pathology of, 351.

- Arsenite of bromine in treatment of, 627.
 Arterial tension, treatment of, 301.
 Arteries, deligation of large, 614.
 Artery, carotid, ligation of, 50; pulmonary, rupture of, 417.
 Artificial nephritis, 296; infant alimentation, 540; coffee, 647.
 Ascaris lumbricoides, iodoform for, 192.
 Ascites, infantile, 246.
 Aspedospermine (Quebracho), 24; administration of, 357.
 Asthma, hay, radical cure of, 708.
 Asylums, lunatic, supervision and control of, 216; and our insane, 553.
 Asthma, 150, 260, 346; cigarettes, 77; nasal disease, cause of, 304; permanent, 642.
 Astley Cooper prize, 475.
 Astragalus, dislocation of, 79.
 Ataxia, locomotor, complicated by, 108; locomotor, galvanic treatment of, 443.
 Ataxy, locomotor, laryngeal accidents of, 281.
 Atmospheric pressure and apoplexy, 190.
 Atrophy; chemistry of acute yellow, 50; muscular of joints, 499; cerebral consecutive to amputation, 696.
 Atropia for earache, 499.
 Auscultation and percussion; physical exploration of lungs by, 132.
 Automatism; human, 194.
 Autopsy; mutual society, 160.
 Azores as a health resort, 449.
 Baby farming in France, 167.
 Bacillus, of measles, 275; tubercle and phthisis, 293; of whooping-cough, 297; mounting, 498; tuberculosis, practical value of, 692.
 Bacteria and puerperal septicæmia, 274.
 Balanitis, 260.
 Balano-posthitis, diabetic, 356; posthitis of diabetics, 615.
 Battery, new universal, 453.
 Beates and McDowell, charges withdrawn, 418.
 Belladonna, and aconite in erysipelas, 80; poisoning, temperature in, 180; a therapeusis in, 570; in gonorrhœa, 589; a prophylactic against scarlet fever, 700.
 Benign growths; removal from, 656.
 Benzoates in uric acid diathesis, 615.
 Beri-beri, 606.
 Beverage and medicine; alcohol as a, 141.
 Bromide of potassium; removing stains of, 358.
 Bile, function of, 49; duct, ligature of, 436.
 Bilharzia hæmatobia, 437.
 Billroth on empyema, 242.
 Bismuth subnitrate for cancrum oris, 192.
 Bladder; fibrous papilloma of, 274; papilloma of, 275.
 Bladder, spontaneous formation of gas in, 698.
 Bleeding to death of fetus during parturition, 26.
 Blennorrhœa neonatorum, to prevent, 643.
 Blenorrhagic pleurisy, 245.
 Blindness; causes and prevention of, 27; prevention of, 83.
 Blisters; iodine in, 384.
 Blood from right heart; abstraction of, 108; pressure, physiology of, 322.
 Board of Health of Illinois, 177.
 Bodies, foreign, swallowed, 81.
 Body-snatchers, 475.
 Bogus diplomas, 53.
 Boluses; Simonnot's anti-blennorrhagic, 304.
 Bone and brain disease in syphilis, 296.
 Boracic acid powder, 194; ointment, 305.
 Bothrioccephalus latus found in, 355.
 Bougies, suppositories, etc., 253.
 Bovine *vs.* humanized virus, 51.
 Bowel; strangulation of, 43.
 Bowels; obstruction of, 22; effect of potash and sodium salts on muscular tissue of, 163; after perineorrhaphy, proper management of, 234.
 Box, the green, 707.
 Boys; hysteria in, 237.
 Brain; study of the face as an index of, 17; tumor of, 100; *post mortem* examinations of, 123; female, work, 166; weight of, 329; and spinal cord, chemical diseases of, 349; abscess at base of, 629; congestion of, 605; medical examination of, 686.
 Brandy, 251; poisoning, 265.
 Brassicon, 329.
 Breast; carcinoma of, 73; tumors of, 656; unusual tumor of, 711.
 Breathing; rapid anæsthesia by, 23.
 Bright's disease; influence of alcohol on, 166; etherization in, 473; pathology of, 491; specimens from case of, 707.
 British Medical Association, 620.
 Bromide of conium; physiological action of, 296; of potassium in chordee, 332; of potassium, action of, 434; of arsenic, 357; of gold in epilepsy, 643.
 Bronchial tubes; stenosis of, 407.
 Bronchocele; large, removal of, 303.
 Buboes; salicylic acid in, 356.
 Buccalis leucoplakia, 328.
 Burns; deaths from and pathology of, 295.
 Butter; preservation of, 250.
 Cæsarian section, 138; operation, 444.
 Caffein for hypodermic use, 330.
 Calabar bean; extract of, 500.
 Calculi, renal and vesical solution of, 699.
 Calcareous particles, passed per vaginam, 600.
 California, a health resort, 173.
 Calomel in laryngitis, 52.
 Calx sulphurata, 60.
 Camphor, enema, 26.
 Cannabis indica, 690.
 Canellata; tania medio, 590.
 Cancer; germ origin of, 73; epithelial ergot in, 109; of cervix, 138; of cervix uteri, 231; of cervix, complicated with, 276; of stomach, 302, 348; rectal colotomy, 349; secondary of liver, 375; of rectum, 375; inheritance of, 462; of the ileum, 498; increase of, 612; of pancreas, 643.
 Cannabine; tannate of, 521.
 Cancrum oris; subnitrate bismuth for, 192.
 Cape May; sewerage system of, 593.
 Capillary; puncture of stomach for, 465.
 Capon Springs, 647.
 Capsule of liver; syphilitic inflammation of, 211.
 Carbolic spray; value of, 385; acid injections in hydrocele and cystic tumors, 406.
 Carbolic acid, in, 670; *vs.* permanganate of potash, 701.
 Carbolized iodoform, 589.
 Carcinoma, of breast, 73; of stomach, 99; histogenesis of, 323; scirrhus of stomach, 396; of breast, 531; renal specimens of, 700.

- Cardiac stimulant; electricity as a, 49; acute disease, locomotor ataxia complicated by, 108; cirrhosis, 354; rheumatic complications, treatment of, 501; vegetations, 641.
- Carditis, myo; lesion of, 295.
- Caries, of superior maxilla, 313; tympanic, producing sub-dural abscess, 706.
- Cartilage, thyroid, fracture of, 63.
- Carotid artery; ligation of common, 50; ligature for, 276.
- Carious tooth; tetanus from, 103.
- Case of cystocele complicating labor, 667.
- Case of transposition of heart, with bronchial catarrh, 1; of dislocation of the wrist, 5; of epilepsy, 26; of gangrena oris, 33; of mitral obstruction, with sequential lesions, 37; of cataract, with complications, 52; of opium addiction, 72; in practice, 80; of organic stricture of urethra, 95; of causalgia, 244; of coccygodynia, with extirpation of coccyx, 287; of polydipsia, 328; peculiar, 351; of neglected presentation of shoulder, 378; of oxaluria, 398; of abdominal cystic tumor, 402; of acute yellow atrophy of liver, 492; of erysipelas neonatorum, 546; of metastatic pneumonia, 546; of venesection, 588; of injury to heart, 640; of obscure fatal nervous disease, 641.
- Caseous swollen lymphatic glands, 24.
- Cases in practice, 32; report all your valuable, 76; of carcinoma of stomach, 99; of antiseptic treatment in puerperal diseases, 309; of abdominal section, 384; of perforation of œsophagus, 472.
- Cases of poisoning, 671.
- Castor oil and glycerine, 469.
- Casts; hardening plaster, 162.
- Catheter, operation without use of, 658.
- Catarrh, bronchial transposition of heart with, 1; acute of nose, 218.
- Catarrhal jaundice, 260; inflammation at, 371.
- Cataract with complications, 52; sympathetic ophthalmia following extraction of, 162.
- Cattaneo's treatment of hydrocele, 416.
- Catheter; improved, 304.
- Cattle diseases, investigations of, 503.
- Caustic applications, anæsthesia by, 639.
- Causalgia; case of, 244.
- Causation of typhoid fever, 697.
- Canterization of clitoris for hysteria, 502.
- Cayenne pepper in glycerine for, 277.
- Cellulitis, orbital, 162.
- Centenarians, 81, 111.
- Central American medical curiosities, 92, 113.
- Cerebellum, glio-sarcoma of, 499.
- Cerebral atrophy, consecutive to amputation, 696.
- Cerebral dyspepsia, 265; aneurism, curability of, 498.
- Cerebro-spinal meningitis, micrococcus of, 589.
- Cerebrum, physiology of, 163.
- Certificates, special, in state medicine, 469.
- Cervix, uterine; polypi from, 101; cancer of, 138, 231; uteri lacerated, 235, 262; pregnancy complicated with cancer of, 276; uteri, laceration of, 339, 612.
- Chamomile, infusion of, 357.
- Chancre; Hunterian of lip, 102; on chin, 385; phagedenic treatment of, 500; indurated between toes, 502.
- Chancres, salicylic acid in, 356; resorcin for, 473.
- Chaulmoogra oil, leprosy treated by, 183.
- Change; tissue in fevers, 217.
- Charbon, malignant vaccination in, 300.
- Charges against Drs. Beates and McDowell withdrawn, 418.
- Charlatan; a dangerous, 83.
- Chemical diseases of brain and spinal cord, 349.
- Chemistry of acute yellow atrophy, 50.
- Chest development by exercise, 82.
- Child, insanity in, 671.
- Children, chloroform in, 108; lithotomy in, 155; lancing gums of, 108; diseases of ear in, 220, 247; tonsillotomy in, 302; nasal polypi in, 607.
- Chin, chancre on, 385.
- China, competitive examination in, 87.
- Chinese physician in New York, 475.
- Chloral in albuminuria, 189; action of, 434; overdose of, 446; hydrate as a vesicant, 471; supposed hydrophobia treated by, 502.
- Chlorinated oil in scabies, 329.
- Chloroma, 708.
- Chlorodyne; tolerance of, 304.
- Chloroform injections in toothache, 671.
- Chloroform narcosis during sleep, 694.
- Chloroform taken with suicidal intent, 306; *vs.* ether, 328; impurities in, 356; water in gastric irritation, 472; breath in gastric disturbance, 582.
- Cholecystotomy, 15.
- Cholera in Mexico, 195.
- Chondroma of skull, 545.
- Chordee; bromide of potassium in, 332; treatment of, 669.
- Chorea, 644.
- Choroid; tubercle of, 156.
- Chronic; intractable cystitis, cure for, 44; gallstones, extirpation of, 356; inversion of uterus, 467; diphtheria, 493.
- Chylocele of tunica vaginalis, 589.
- Cicatrices; abscesses of neck relieved without, 303.
- Cigarettes; asthma, 77.
- Cinnamon-colored clothing; danger from, 302.
- Circulation; action of thymol on, 191.
- Cirrhosis, 455; of the liver, 50.
- Cirrhosis, cardiac, 354.
- Clamp pile, 250.
- Clairvoyants; consulting, 417.
- Clavicle, fracture of, 66.
- Climacteric dyspepsia, 501.
- Clinical studies of inebriety, 88, 169; lectures on diseases of women, 337.
- Clitoris for hysteria; canterization of, 502.
- Club-foot, 526.
- Co-education of sexes, 350.
- Coat-sleeve amputation, 614.
- Coccygodynia, with extirpation of coccyx, 287.
- Code; the new, 137, 474; of New York, 306, 390.
- Coffee, in typhoid fever, 502; artificial, 647.
- Coffins; glass, 335.
- Cold baths in typhoid fever, 611; antithermic treatment by, 622.
- Cold douche, 502; taking, 642.
- Coldest town in the world, 194.

 Hammond prize, 279.
 Handedness, right, 418.
 Hay asthma, radical cure of, 708.
 Headache, sick, 116; cause of, 25.
 Health; National Board of, 83, 107; State Board of, 136, 355; influence of electric light on, 163; resort, California as, 173; Board, State, of Illinois, 177; Association, American Public, 306; report of Paris, 355, 497; resort, Azores a, 449; legislation in Ohio, 503.
 Healthfulness of seashore resorts, 201.
 Healthiness of Washington City, 315.
 Hearing, anomaly in, 702.
 Heart; transposition of, with bronchial catarrh, 1; rupture mistaken for, 37; lungs and gall bladder, sarcoma of, 40; puncture and suture as therapeutic procedures, 154; disease, conval-laria majalis in, 211; sounds of, 298; rupture of, 305; malignant tumor of, 350; essential nature of diseases of, 493; effect of salicylate of sodium on, 495; injury to, 640.
 Heathen lands, medical missions in, 2, 29.
 Hegar's operation, 238.
 Heloderma horrida, 206; suspectum, partial study of, 319.
 Hemorrhage; uterine appendages, removal for, 155; ligature of, 276; dangerous, from external genitals during labor, 385; puerperal, secondary, 408; non-puerperal uterine, 434; from, 613.
 Hemorrhagica purpura, 544.
 Hemorrhages and salicylates in enteric fever, 351, 382, 443.
 Hemorrhoids, intero-external, 66.
 Hepatic; abscesses, indicative of, 304; diseases, treatment of, 383; abscess, 694.
 Hernia; radical cure of, 22; femoral, 551; diaphragmatic, 152; inguinal, radical cure of, 237; reduced by electricity, 494.
 Hereditary and rachitis syphilis, 677.
 Hiccough, persistent, 579.
 Hip disease cured, 344.
 Hip-joint, superiostial amputation at, 614.
 Histogenesis of carcinoma, 323.
 Hives, 53, 165.
 Horrida, heloderma, 206.
 HOSPITAL REPORTS.—
Bellevue Medical College.—
 Clinic of Prof. L. A. Sayre, 8, 66, 344, 484.
 Clinic of Dr. E. G. Janeway, 576.
Hospital College of Medicine, Louisville, Ky.—
 Clinic of Dr. J. A. Larrabee, 317, 596.
Medico-Chirurgical College.—
 Clinic of F. O. Nagle, M. D., 34.
Michigan College of Medicine, Detroit.—
 Clinic of C. J. Lundy, M. D., 175.
New York Hospital.—
 Clinic of Prof. W. H. Draper, 150, 260, 346, 402, 455, 544.
Pennsylvania Hospital.—
 Clinic of J. H. Huthison, M. D., 371.
 Clinic of T. G. Morton, M. D., 423.
State Hospital, Prague.—
 Clinic of Prof. A. Pribram, 7.
City Hospital, Prague.—
 Clinic of Prof. F. O. Pick, 631.
St. Louis College of Physicians and Surgeons.—
 Clinic of Jos. L. Bauer, M. D., 95.
 Clinic of Francis Delafeld, M. D., 289.
University Hospital.—
 Clinic of J. Ashhurst, Jr., M. D., 64, 127.
 Clinic of C. K. Mills, M. D., 123.
 Clinic of Dr. Wm. Goodell, 231.
Philadelphia Hospital.—259.
 Clinic of Dr. J. M. Keating, 400.
West Pennsylvania Hospital, Pittsburgh, Pa.—
 Clinic of Dr. F. Lemoyne, 629.
Charity Hospital, Cleveland, Ohio.—
 Clinic of Dr. R. A. Vance, 656.
Michigan College of Medicine.—
 Clinic of Dr. D. Laferté, 684.
Hospice de la Salpetriere.—
 Clinic of M. Baillarger, 685.
 Hospital at almshouse, 111.
 Hot pack in puerperal eclampsia, 328.
 Hot soda, 363.
 Hot water retrojection in gonorrhœa, 551.
 House-plants and lung disease, 560.
 How to make a poultice, 22.
 Human; automatism, 194; teeth, agency of micro-organisms in decay of, 266.
 Humanized virus vs. bovine, 51.
 Human body, parasites in, 674.
 Humerus, gunshot fracture of, 485.
 Hunt—Esmarch—Garfield, 55.
 Hunt's satire, 83.
 Hunterian chancre of lip, 102.
 Hydatid; of the liver, 182; cyst in prostrate gland, 357.
 Hydrargyrum formidatum in syphilis, 238.
 Hydrate, chloral, as a vesicant, 471.
 Hydrocele; tapping, 128; and cystic tumors, carbolic acid injections in, 406; treatment of, 416; its radical treatment, 426.
 Hydrocephalus, 596.
 Hydrophobia; meat, 82; prevention of, 242; supposed treated by chloral, 502.
 Hydrotherapy, in treatment of syphilis, 385.
 Hydrargyrum formidatum, 698.
 Hygienic management of consumption, 560.
 Hygiene and sanitary medicine, 363; public, 520.
 Hymen, imperforate, 668.
 Hyperidrosis of hands and feet, 502.
 Hypertrophic elongation of supravaginal portion of cervix, 231.
 Hypertrophy; compensatory, of kidney, 239; of the nails, 643.
 Hypodermic use, purgatives for, 191; caffeine for, 330; injections of ether in, 636.
 Hypnotic; ozonized air as a, 26; slumber, rape during, 183; paraldehyde as an, 304.
 Hysteria in young boys, 237; cauterization of clitoris for, 502.
 Hysterectomy, 414, 587.

- Hyoscyamine, therapeutic effects of, 23.
 Ichthyol in skin diseases, 433.
 Idiopathic spasm of glottis, 79; erysipelas in infant, 435.
 Idiot, stomach of, 245.
 Ileum, cancer of, 498.
 Ileus, treatment of, 670.
 Iliac arteries, aneurism of the external, 632.
 Illinois State Board of Health, 177.
 Illustrations of rare skin diseases, 444.
 Imperforate hymen persistent in labor, 668.
 Importance attached to karyokinesis, 49.
 Improved vaginal douche, 137; catheter, 304.
 Improvement in therapeutics, 419.
 Impurities in chloroform, new test for, 356.
 Incubation of measles, period of, 502.
 Index of the brain, study of the face as an, 17.
 Indian treatment of syphilis, 443.
 Indica, cannabis, 690.
 Indications for use of different kinds of electricity, 189.
 Induction, of premature labor for, 347.
 Indurated chancre between toes, 502.
 Inebriety; treatment of, by moral means, 88; trance, state of, 283; clinical studies in, 88, 169.
 Infant; idiopathic erysipelas in, 435; artificial alimentation, 540.
 Infants, syphilitic ulceration of conjunctivæ in, 42.
 Infantile therapeutics; nux vomica and strychnine in, 14; ascites, 246; leucorrhœa, 337; diarrhœa, chamomile for, 357.
 Infected milk, epidemic of diphtheria from, 239.
 Infectious; disease, acute pneumonia an, 50; diseases, notification of, 270; diseases, new reaction of urine in, 328; diseases, treatment of, 690.
 Inferior vena cava, occlusion of, 465.
 Inflammation; syphilitic, of capsule of liver, 211; catarrhal at apex of left lung, 371.
 Influence, of constitutional diathesis on the development of disease germs, 57; of alcoholism, 664.
 Infra orbital nerve, best method of, 423.
 Infusion of chamomile as, 357.
 Inguinal hernia, radical cure of, 237.
 Ingenious device for supporting a hospital, 419.
 Inhalations, antiseptic, in phthisis, 669.
 Inheritance of cancer, 462.
 Inhibited development, explanation of, 613.
 Injections ether *vs.* transfusion, 138; subcutaneous, of resorcin in erysipelas, 351; of ether, paralysis from, 445.
 Injudicious use of quinine, 302.
 Injuries, *post mortem* from insects, 363.
 Injuring teeth by tobacco, 328.
 Injurious effects on health of aniline dyes, 548.
 Ink, faded, to restore, 335.
 Inoculation of syphilis, 156.
 Inosuria, 436.
 Insane, protection of, and prevention of insanity, 106; national association for protection of, 54; women, utero-ovarian disease in, 473; hospitals, medical service of, 535; and our asylums, 553; colony at Gheel, 585.
 Insanity, domesticity a cause of, 82; temporary; 107; national association for prevention of, 139; trephining for, 472; in child, 671.
 Insects, *post mortem* injuries from, 363.
 Inspidus, diabetes, ergot in, 670.
 Inspection, sanitary, of schools, 135.
 Instruction in mental diseases, 300; to German midwives, 383.
 Instrumental compression, popliteal aneurism cured by, 344.
 Insufflation in treatment of ileus, 670.
 Insurance, Lamson life, 194.
 Intermittent symptoms, 685.
 Intermittent fever, faradization of spleen in, 190; treatment of, 371; epidemic of, 440; spinal paralysis, 164; anti-quinine treatment of, 697.
 International Medical Congress, 101.
 Intero-external hemorrhoids, 66.
 Interstitial tubo, gestation, 413.
 Intestinal polypi, 180; obstruction treated by rectal tube, 244; obstruction, surgical treatment of, 417.
 Intestines, ulceration and perforation of, 471; human, larvæ of flies in, 471; motions of, 665.
 Intractable chronic cystitis, cure for, 44.
 Inversion of sexual sense, 436; chronic, of uterus, 467.
 Investigation, collective of disease, 215.
 Iodia, 675.
 Iodide of potassium in laryngitis, 52; poisoning, 474.
 Iodine; spina bifida cured by injections of, 329; in typhoid fever, 330; blisters in tabes mesenterica, 384; tincture of, in treatment of hydrocele, 426; an antidote for snake bite, 589; for vomiting, 615.
 Iodoform, 49; to disguise odor of, 51, 192; in diphtheria, 159, 258, 446; for ascaris lumbricoides, 192; a local application in, 399; in puerperal fever, 415; proper way to use, 497; suppositories in, 500; in laryngeal ulcers, 502; in diabetes, 589; carbolized, 589; suppositories for puerperal septicæmia, 635; dressings in lesions of peritoneum, 640; treatment of phthisis by, 662.
 Iris, gummy tumor of, 175.
 Iritis, double, due to rheumatism, 175.
 Iron, tincture, prophylactic influence on contagious diseases, 189; dialyzed, 266; perchloride in skin diseases, 437.
 Irregular contractions of uterus, 611.
 Irritation; preputial convulsions caused by, 316; gastric, chloroform water in, 472.
 Isle of Reil, lesions of, 272.
 Itch, naphthol in, 414.
 Items, therapeutic, 274.
 Jaundice, catarrhal, 260.
 Jaw, luxation of, 54.
 Jefferson Medical College, 391.
 Jequiriti, in treatment of, 230.
 Journals of Paris, 306.
 Journalism; the value of practical medical, 21; medical, the mission of, 298.

 Prolapsus recti, treatment of, 276.
 Prolonged antiseptic baths, 548; suspended animation, 693.
 Prophylactic influence of tincture of iron on contagious disease, 189.
 Proposed sanitary convention, 178.
 Prostate gland, hydatid cyst in, 357.
 Prostatic retention of urine, cure for, 44.
 Protective, a new, 417.
 Protection, of insane and prevention of insanity, 107; from yellow fever, 412.
 Prostitution, 496; regulation of, 363; in France, 640.
 Pruritis vulvæ, 385; urethræ during gonorrhœa, 500.
 Pseudo-epilepsy, malarial, 711.
 Pseudo-leukæmia and, 694.

- Pseudo-membranous croup, treatment of, 80.
 Psoas muscle; abdominal aneurism rupturing into, 321.
 Psychosis, uræmic, 213.
 Ptosis, new operation for, 356.
 Pubis, phthisiasis, 578.
 Public hygiene, 520.
 Puerperal, eclampsia, 11; pilocarpin in, 303; hot pack in, 328; septicæmia, 582; peritonitis with metastatic abscesses, 23; and bacteria septicæmia, 274; diseases, antiseptic treatment in, 309; hemorrhage, secondary, 408; fever, iodoform in, 415; non-uterine hemorrhage, 434; septicæmia, iodoform suppositories in, 500, 635; fever, 670.
 Puerperalis, micrococcus, 191.
 Pulmonary congestion; abstraction of blood from heart, relieving intense, 108; tuberculosis, early diagnosis of, 138; consumption, mullein plant in, 330; artery, rupture of, 417; syphilis, 489.
 Pulsation of spleen in aortic incompetence, 244; abdominal, 549.
 Puncture of gravid uterus during ovariectomy, 219; capillary, of stomach, for, 465.
 Purgatives for hypodermic use, 191.
 Purpura hemorrhagica, 544.
 Purulent pleural effusions, treatment of, 532.
 Pustule, malignant, 691.
 Pyæmia from syphilitic bone disease, 133.
 Pylorus, excision of, 416; digital divulsion of, 551.
 Pyogallic acid in phagedæna, 191; in eczema, 552.
 Quarantine against syphilis, 48.
 Quassine, 329.
 Question in pathology, 164.
 Quinine; to hasten the action of, 82; free, 166; expensive, 167; disguise taste of, 302; injudicious use of, 302; endermatic use of, 305; deafness from use of, 342; on the ear, action of, 437; subcutaneous injection of, 700; sulphate of, 685.
 Rabies, 182.
 Rachitic diathesis, 400.
 Rachitis and hereditary syphilis, 677.
 Rachitism and syphilis, 380.
 Radical cure of hernia, 22; of popliteal aneurism, 34; of inguinal hernia, 237.
 Rag sorting and small-pox, 76.
 Rape during hypnotic slumber, 183.
 Rapid breathing, anesthesia by, 23.
 Rare sequelæ of enteric fever, 408.
 Rarefied air, action of, 377.
 Rash, morbillic in typhoid fever, 697.
 Rectal tube, intestinal obstruction treated by, 244; cancer, colotomy, 349.
 Recovery from tetanus, 26.
 Rectum; syphilitic stricture of, 128; cancer of, 375.
 Rectus externus, divergent squint corrected by section of, 176.
 Recumbent position in typhoid fever, 229.
 Recurrence of scarlatina within, 328.
 Recurring attacks of pelvic peritonitis, 338.
 Recurrent hæmaturia, 470.
 Regulating practice of medicine in Minn., 674.
 Regulation of prostitution in, 363.
 Religion of Darwin, 161.
 Removal; of a colossal tumor, 71; of gangrenous testicle, 103; of uterine appendages for arrest of hemorrhage, 155; of tape-worms, 286, 423; of stains of bichromate of potassium, 358; of benign growths from, 656.
 Remedy; new, in diphtheria, 188; for syphilis, 218; in menorrhagia, valuable, 690.
 Renal carcinoma, specimens of, 700.
 Repetition of doses, 332; Prof. Smith's frequent, 417.
 Report all your valuable cases, 76.
 Reposition of inverted uterus, 473.
 Researches; Pasteur's, 81.
 Resection of stomach, 444.
 Resorcin; subcutaneous injections in treatment of erysipelas, 351; for chancres, 473; methods of administering, 669.
 Resort, health, California as, 173.
 Resorts, seashore, healthfulness of, 201.
 Respiratory; murmurs, origin of, 383; muscles, 576.
 Restoration of frozen persons, 277.
 Restore faded ink, 335.
 Retention of urine, prostatic, cure for, 44.
 Retinitis, neuro, 499.
 Retrojection, hot water in gonorrhœa, 551.
 Revaccination, efficacy of, 527; value of, 698.

Stab of pericardium, diaphragm, and liver, 38.

Starch; elementary composition of, 79; in milk, to detect, 536.

State; and National Board of Health, 83, 355-Board of Health and its duties, 136; of Wis, consin, 583; medicines, special certificates in; 469.

Statistics; relating to consumption, 55; and allied features of diphtheria, 119; mortality, 651.

Stenosis; of trachea and bronchial tubes, 407; mitral, treatment of, 565.

Sterility; and labor, effect on, 262; Dr. Duncan on, 580; alcoholism, cause of, 612.

Stigmata of maize, extract of 103.

Stimulation, electrical of the uterus, 237.

Stinging tree, 363.

Stomach; carcinoma of, 99; ulcer of, in anterior wall, 153; of an idiot, 245; cancer of, 302, 348; scirrhus carcinoma of, 396; capillary puncture of, 465; resection of, 444; affection of, 612; ulcer of, 661.

Stone in female bladder, 600.

Strabismus cured by glasses, 494.

Straight-bodied position in labor, 78.

Strangulation of the bowel, 43.

Stretching, nerve, 304.

Striatum, corpus, osteoma of, 499.

Stricture; organic, of urethra, 95; syphilitic, of rectum, 128; and abscess of œsophagus, 145.

Struggle for a living, 502.

Struma, 204.

Strychnine and nux vomica in infantile therapeutics, 14.

Strychnine, morphine poisoning treated with, 110.

Studies, clinical, of inebriety, 88.

Study of face as an index of the brain, 17.

Stye, to abort, 588.

Styptic, plantago lanceolata as, 303; new, 700.

Subcutaneous; injections of resorcin in erysipelas, 351; injection of nitro-glycerine, 644; nodules and cardiac vegetations, 641; injection of quinine, 700.

Sublimate, corrosive, 273.

Subnitrate of bismuth for cancerum oris, 192.

Sub-mucous chloroform injections in toothache, 671.

Sub-periosteal amputation at hip-joint, 614.

Subinvolution and antelexion in, 339; of uterus, 699.

Suffocation, death from petroleum by, 192.

Sugar; watermelon, 54; in system, physiology of, 297; in urine, detection of, 689.

Suicidal intent, ounce of chloroform taken with, 306.

Sulphate; of zinc, pencil of, 502; of quinine, properties of, 622; of quinine, cure by, 685.

Sulphur; as disinfectant, 162; in diphtheria, 193; preparations in acne, 654.

Sulphurata, calx, 60.

Sulphurous acid in scarlatina maligna, 463.

Superior maxilla, caries of, 313.

Supervision and control of lunatic asylums, 216.

Suppositories, bougies, etc., 253; ergotine, 245; iodoform, for puerperal septicæmia, 635; in chronic cystitis, 698.

Suppurating cyst of, 603.

Supra-vaginal hypertrophic elongation of cervix, 231.

Surgical treatment; of caseous swollen lymphatic glands, 24; of intestinal obstructions, 417.

Surgery; expectant treatment in, 102; electric light in, 242, 442; address in, 537; trance condition in, 637.

Suspectum, heloderma, study of, 319.

Sustained muscular effort, 384.

Suture in Cæsarian section, peritoneal uterine, 468.

Swallowed foreign bodies, 89.

Swallowing shot and insufflation in, 670; silver half-dollar, 700.

Sympathetic ophthalmia following extraction of cataract, 162; nerve in, 570.

Sympatheticus, symptom of lesion of, 642.

Syndectomy for pannus, 644.

Synovitis, tuberculous of tendons, 23.

Synthesis of salicin, 357.

Synthesis of uric acid, 350.

Syphilis; quarantine against, 48; visceral hæmatemesis due to, 78; inoculation of, 156; new remedy for, 218; epidemic of, 223; hydrargyrum formidatum in, 238; bone and brain disease in, 296; in the female, 354; and rachitism, 380; hydrotherapy in treatment of, 385; treatment of, 441, 587; Indian treatment of, 443; in monkeys, 473; pulmonary, 489; complicated with malaria, treatment of, 497; second infection with, 502; spleen in, 547; in America, 552; in woman, difficulty of detecting true, 642; excision of primary sore in, 643; rachitis and hereditary, 677; and rickets, 697. Syphilitic; ulceration of conjunctivæ in infants, 42; enlargement of tonsils, 104; stricture of rectum, 128; bone disease, pyæmia from, 133; disease of knee-joint, 180; inflammation of capsule of liver, 211; gumma in the liver, 329.

Tabes; mesenterica, 317; iodine blisters in, 384.

Tænia, medio canellata in, 590.

Talipes, equino-valgus and equino-varus, 8.

Tannate of cannabine, 521.

Tape-worms, removal of, 286, 423.

Teeth injured by tobacco, 238.

Telegraph, prescribing by, 363.

- Temperature; in belladonna poisoning, 180; of body in, 385.
- Temporal bone, metastatic pneumonia following pistol-shot wound of, 546.
- Temporary insanity, 107.
- Tendons, tuberculous synovitis of, 23.
- Tension, arterial treatment of, 301.
- Test, for albumen, 669; papers, detection of sugar in urine by, 689.
- Testicle, gangrenous removal of, 103.
- Tetanus; recovery, 26; from carious tooth, 103; in typhoid fever, 245; fatal, complicating typhoid fever, 385; or worms, 683.
- Therapeutic; effects of hyoscyamine, 23; procedures, heart puncture and suture as, 154; items, 274; progress, 329; improvements, 419, 675; value of nitro-glycerine, 694.
- Therapeutics, *nux vomica* and strychnine in infantile, 14; liver diseases, local, 51.
- Thigh bone, fracture of, 65.
- Thoracic duct, thrombosis in, 472.
- Throat, diphtheritic sore, treatment of, 24; electric light, 536.
- Thrombosis in thoracic duct, 472.
- Thrush in typhoid fever, development of, 270.
- Thymol, on circulation, action of, 191.
- Thyroid cartilage, fracture of, 63.
- Tibia, necrosis of, 128.
- Time wasted in drug stores, 300.
- Tincture of iron, prophylactic influence of, 189.
- Tinea tonsurans solution, cayenne pepper in glycerine for, 277; versicolor, 696.
- Tissue changes in fevers, 217.
- Tobacco, teeth injured by, 238; consumption of, 405.
- Toe nails, hypertrophy of, 643.
- Toes, indurated chancre between, 502.
- Tolerance of chlorodyne, 304; of opium, 316.
- Tonic, alterative, 445.
- Tonsils, syphilitic, enlargement of, 104.
- Tonsillotomy in children, 302.
- Tooth; carious tetanus from, 103; ache, chloroform injection in, 671.
- Topical effects of kerosene, 446.
- Trachea and bronchial tubes, stenosis of, 407.
- Tracheotomy, 79.
- Trance state of inebriety, 283; condition in surgery, 637.
- Transfusion, 687; *vs.* ether injections, 138; of saline solutions in acute anemia, 465; of diphtheria, 471.
- Transplantation of skin-flaps, 711.
- Transposition of heart with bronchial catarrh, I.
- Traumatica, urethritis, 256.
- Treating ulcers, new method of, 472.
- Treatment of sexual neurasthenia, 15; of diphtheritic sore throat, 24; of fracture of patella, 51; of the pedicle, 69; of croup, 78, 670; of diphtheria and pseudo-membranous croup, 80; of wounded in Egypt, 83; of inebriety by moral means, 88; of organic stricture of urethra by continuous dilatation, 95; expectant in surgery, 102; of diphtheria, 110; of scarlet fever, 110; of morphine poisoning with strychnia, 110; of enteric fever, 129; of leprosy by chaulmoogra oil, 183; of nocturnal enuresis by, 190, 268; by Weir-Mitchell, 241; of gonorrhoea, 245; of delirium tremens, 273; of acne rosacea, 276; of typhoid fever, 276, 477, 350, 621; of prolap-sus recti by, 276; of Meniere's disease, 277; of rosacea by leeching, 277; of increased arterial tension, 301; antiseptic in puerperal diseases, 309; of obstinate neuralgia, 329; of granulation of conjunctiva, jequiriti in, 330; of cough and expectoration, 331; of erysipelas by, 351; of pneumonia, 357; of intermittent fever, 371; of hepatic diseases, 383; of syphilis, hydrotherapy, 385; of oxaluria, 398; of acute rheumatism, 411; of enlarged glands, 414; of dysentery, 415; of hydrocele, 416, 426; of intestinal obstruction, 417; of whooping-cough, 421; of syphilis, 441, 587; Indian, of syphilis, 443; of locomotor ataxia, 443; of spermatorrhoea, 463; of apoplexy, 470; of syphilis, complicated with malaria, 497; of phagedenic chancre, 500; of rheumatic, cardiac complications, 501; of purulent pleural effusions, 532; of mitral stenosis, 565; of parturition, 613; and pathology of tuberculosis, 636; of gouty pains and neuralgia by, 644; of variola, 655; of phthisis by iodoform, 662; of chordee, 669; of ileus, 670; of infectious diseases, 690; of granular lids, 695; anti-quinine of intermittent fever, 697; of erysipelas, 698.
- Tree, a stinging, 363.
- Tremens, delirium, treatment of, 273.
- Trephining for insanity, 472.
- Trichiiasis, electrolysis in partial, 43.
- Tubal pregnancy, 445.
- Tubercle of choroid, 156; bacillus and phthisis, 293; disinfection of, 436.
- Tuberculosis of spleen, liver and kidneys, 97; pulmonary, early diagnosis of, 138; parasitic, a disease? 184; treatment and pathology of, 636; synovitis of tendons, 23; bacillus, practical value of, 692.
- Tube-gestation, interstitial, 413.
- Tumor; gouty, of penis, 49; colossal, removal of, 71; of brain, 100; condylomatous, of labium, 152; of head of pancreas, 152; gumming of iris with iritis, 175; malignant, of heart, 350; of milary tubercles of, 376; cystic abdominal, history of, 402; myxomatous, of chest, 707; unusual, of breast, 711.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

☞ *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.

Office, N. E. Cor. Tenth and Arch Sts.,

PHILADELPHIA.

~~33~~ We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from \$15 to \$30, according to the number of currents. 13-7-131

A CASE OF TRANSPOSITION OF THE HEART
AND OTHER ORGANS, ACCOMPANIED
WITH BRONCHIAL CATARRH.

BY THOS. S. SOZINSKEY, M. D., PH. D.

I have had under observation for several years a girl, Katie O'N——, aged $9\frac{1}{2}$ years, who has been affected with more or less bronchial catarrh ever since birth, the cause of which appears to have been, directly or indirectly, the anomalous position of her heart and other parts. She has never suffered from any acute disease, save a mild attack of measles, and her lungs are sound structurally. In fact, there is no reason to doubt that the position of the heart is congenital. Her height is forty-four inches and her weight forty-two pounds. Her chest measures twenty-two and a half inches, and is symmetrical. In comparison with other children, she is considerably below the average in both height and weight (about five inches in the former and fifteen pounds in the latter), and a sister, who is over two years younger, is over an inch taller and about the same weight. She is seemingly as active and mentally as bright as most other girls of her age.

The apex-impulse of the heart is at the lower edge of the fifth rib and slightly to the left of the line of the nipple. Indeed, the organ is apparently perfectly transposed. The sounds, as well as the size of it, are normal, but there is a slight tendency to palpitation, the pulse being habitually from 90 to 100 per minute. This tendency may have something to do with the catarrh; still, it is impossible to say exactly why the latter exists.

The liver is on the left side. This is sufficiently evident from the area of dullness on percussion on that side and the state of resonance on the other. Whether the stomach and intestines, etc., are reversed in position, I cannot say definitely, but I believe they are. The spleen seems to be in its usual position.

The catarrh has never been very decided. Little has been done for it at any time. Whether it will ever disappear is a question which probably time alone can answer.

The girl is markedly left-handed. None of her people have been so. It would seem that left-handedness is common, if not the rule, in persons with transposed heart. In the case referred to later, reported by Dr. Augustus Wilson, there was left-handedness. Dwelling on this, the doctor, with too little regard for the opinions of the modern philosophers, contends that right-handedness is due solely to training. Hereditary tendency has doubtless something to do with it. What is said above gives some support to Hyrtl's theory, that it is due to circulatory conditions.

Speaking of congenital misplacements of the heart, in his work on pathological anatomy, Rokitsky says: "Actual transposition may exist with reference to the heart alone, or concurrently with the thoracic and abdominal viscera generally." But little more information than this, on the subject, is to be found in the books.

In his treatise on the diseases of the heart and great vessels, Dr. Walshe says: "Except in very rare instances, when the heart has formed and grown on the wrong side of the spine, the abdominal viscera also have been transposed." This is given as the chief guide to the recognition of con-

genital, in contradistinction to acquired misplacement of the heart.

Although a statement in Dr. Flint's work on diseases of the heart might leave a contrary impression, cases of transposition of the heart and other viscera are rare. Dr. Stokes, in his work on diseases of the heart and aorta, expresses the idea that such cases are very rare. A report, by Dr. Wilson, of a *post mortem* examination of a case which was met with in one of the hospitals of this city, appeared in the issue of this journal for November 11. The first case noticed during life was one which came under the observation of M. Durand, 1666; and the first detailed examination of such a case, *post mortem*, was made by Dr. Allen Thompson, an account of which is given in the *Glasgow Medical Journal*, 1853.

In this connection I may give the following interesting letter which I have received, in reply to some inquiries, from the distinguished professor of Pathology and Practice of Medicine, in the College of Physicians and Surgeons of New York, Dr. Alonzo Clark:

"*Dear Doctor*: The cases in which the heart is found on the right side and the liver on the left are rare. In a long professional lifetime, and almost all of it in hospital, as well as consultational practice, I have known but two cases. One was in a very intimate professional friend, who lived to near 60 years of age, and died of the spinal disease known as locomotor ataxia. He was one of the most accomplished men of the age, and wrote a book that was universally regarded as standard and classic on the Fevers of the United States. He never had a sensation that suggested any heart or liver disease. I saw him almost to the last hours of his life. The other I saw for the first time at mature life, and had no opportunity of following him to the end. I do not know of any treatise on the subject, though it is occasionally referred to in the text-books. Yours, A. CLARK."

It may not be amiss to say that the physician to whom Dr. Clark refers was, doubtless, Dr. Elisha Bartlett, who was born in Rhode Island, October 6th, 1804, and died July 19th, 1855. He was a professor in various colleges, including the University of New York and the College of Physicians and Surgeons. In addition to "The History, Diagnosis and Treatment of the Fevers of the United States," the 4th edition of which was issued in 1856, under the editorship of Dr. Clark, he wrote an octavo of 312 pages in advocacy of empirical practice, entitled "An Essay on the Philosophy of Medical Science," a copy of which happens to be in my library, and a volume of poems.

Dr. Flint says of transposition of the heart and

other viscera: "This abnormality is not incompatible with health and long life." Dr. Clark would seem to share this opinion.

As to the cause or causes of congenital transposition of the heart and other organs, nothing definite can be said. There is no ground for believing that it is in the nature of a "reversion;" but it may be observed that in lower animals, and also in the human infant, the heart rests at or near the middle line of the chest. In answer to some inquiries in respect to this interesting point, I have received from Prof. Joseph Leidy, who, I need hardly say, knows whereof he speaks, the following instructive and decisive note:

"*Dear Doctor*: In answer to your note of December 6th, received last evening, in *most* mammals, (see Owen's *Comp. Anat.* III. 525) or animals of our class, the axis of the heart is parallel or nearly so with the median line of the body, and in birds, etc., is always so. The heart in no animal occupies either the right or left side, but in all occupies a mesial position, with the apex backward or diverted more or less to the left. The abnormal reversion of this position cannot be looked upon as a reversion to a natural position in other animals, because such does not exist.

"Respectfully, JOSEPH LEIDY."

"*Phila., Dec. 9th, 1882.*"

MEDICAL MISSIONS IN HEATHEN LANDS.

BY M. P. BARKER M. D.,
Of New Castle, Pa.

One might reasonably suppose that an attempt to overthrow the false systems which prevail so universally in all heathen lands—comprising a very large proportion of the race—would be preposterous. But, notwithstanding the magnitude of the enterprise, it has been undertaken and great results have already been achieved.

In the accomplishment of these results, the medical profession has performed a very great and important work, the labors and achievements of which are worthy of record in the history of the world's progress. In giving a brief account of

MEDICAL WORKERS AND WORK,

I shall confine myself principally to India and China; they being the great fields of philanthropic effort, and typical to a very great extent of other lands.

The first attempt to qualify and send medical missionaries to heathen lands, that we have any record of, was made by

GENERAL CODRINGTON, of the British army. In 1701 he bequeathed property in the West Indies, from which there

was an annual income of ten thousand dollars, to the "Society for the Propagation of the Gospel in Foreign Parts." This income was to be used to establish and maintain on his plantation a school, the purpose of which was set forth as follows: "The professors and students were required to study and practice physic and chirurgery as well as divinity; that by the apparent usefulness of the former to all mankind, they may both endeavor themselves to the people, and have the better opportunity of doing good to men's souls, whilst they are taking care of their bodies."

This bequest did not accomplish all that was expected from it; but as a conception of the best method of conducting the missionary enterprise, it deserves honorable mention, and a place in the history of medical missions.

DR. JOHN THOMAS,

an English surgeon, spent from 1787 to 1792 in Calcutta, in endeavoring to improve the condition of the Hindoos. He then made a visit to England, returning in 1793, taking the devoted Carey with him. The history of his labors and success is meagre, but it was said of him that, "he had exquisite pleasure in doing good, and that multitudes of the poor Hindoos received the benefit of his skill."

In 1821, the Baptist Association of this country sent

REV. JONATHAN PRICE, M. D.,

to Burmah. He settled in Rangoon, where he immediately commenced work. There was nothing remarkable in his career, with the exception that he had been but a few months in Rangoon, when the King, having heard of his success in the treatment of disease, especially of ophthalmia, "ordered that he should visit the Capital." So he set out at once for Ava, taking Mr. Judson with him as interpreter. They reached Ava September 27th, and were immediately introduced to the King. Mr. Judson, in giving an account of their reception, said: "The King received Bro. Price very graciously, and made many inquiries about his medical skill, but took no notice of me except as an interpreter." After this they had interviews with the King nearly every day, and also with the various court officials, who asked many questions about astronomy, religion, etc. The result of these interviews with the King was that he requested them to remain in Ava, and gave them ground to build houses on.

Not long after this, war having broken out between England and Burmah, they were imprisoned, suffering extremely for months, but were at length released and sent for daily to the palace for con-

sultation, nothing being done without their approbation. They were also sent as ambassadors, in company with some English and native officials, and finally succeeded in arranging terms of peace.

Rev. Judson left soon after peace was declared, but Dr. Price settled in Ava, built a house, and there spent the remainder of his days.

On the 27th of May, 1830, after a perilous journey of eight months, in which there were two shipwrecks, the

REV. ALEXANDER DUFF

arrived in Calcutta, being the first Scotch missionary to India. His educational policy, which consisted in the establishment of a college in Calcutta, in which the English language as well as the native dialects were taught, has accomplished more than his most ardent supporters had anticipated, and the results have proven his wise foresight, that it would be the means of overthrowing caste.

This is not the place to record his successful educational career, excepting in so far as it related to his efforts for the abolition of the Native Medical College, and the establishment of a new one under European physicians, and also in the overthrowing of the Bhoido, or physician caste. He was not a physician, but the history of the advancement of medical science in India, during the last half century, would not be complete without recording his efforts in its behalf.

In 1822, the government being anxious to secure

NATIVE SURGEONS FOR THE ARMY,

established a medical college, under an English doctor and native assistants, in Calcutta. Medical classes were formed at the Sanscrit college, to read Charaka and Susruta, and at the Madrasse to study Aricenna and the other Arabic writers.

Doctor Tytler was the head of the institution, and was said to be a most fanatical Orientalist. The only anatomical instruction he dared to give, however, was from models taken from the lower animals and an occasional *post mortem* examination. He declared that this prejudice against dissecting a human body could not be overcome. Duff protested against what he called Dr. Tytler's "folly." "Only use English as the medium," he declared, "and you will break the backbone of caste, you will open up the way for teaching anatomy and all other branches fearlessly; for the enlightened native mind will take its own course, in spite of all the threats of Brahmanical traditionalists."

In 1833, Lord William Bentinck, in view of the deplorable condition of medical education, appointed a committee to investigate and report on this whole subject. This committee was composed

of Surgeon J. Grant, the Apothecary-General; Assistant Surgeons Bramley and Spens, Baboo Ram, Komul Sen, T. C. C. Sutherland, the Secretary to the Committee of Public Instructions, and Sir C. Trevelyan.

This committee, after deliberating for twelve months, and exceedingly anxious to raise a class of of native practitioners, being unable to come to a solution of this question, called upon Mr. Duff. A most animated discussion took place between him and the Superintendent of the Native Medical Institution. It was little wonder that the "fanatical Orientalist," pleaded for the system of the Bhoido caste. Did not their savans possess all knowledge? Were not their Vedas infallible? Had they not been more than the peers of other nations in philology, and in philosophy? Had they not given to the West the knowledge of numbers, even down to the numerals? He could point to the discovery of a remedy for snake-bite—to the fact that they had taught Europeans the operation of rhinoplasty—that their common Bhoidos had performed the operation of lithotomy, and that European princes had sent to them for oculists to remove cataracts—and also that their Vedic Hindoos were the teachers of Pythagoras, Plato, Aristotle, and Hippocrates. No wonder that he predicted failure if Duff's suggestions should be received and put into practice. But, on the other hand, he was confronted with the fact that their native college was a failure, and that their medical knowledge had retrograded rather than advanced, and that it was in a most deplorable condition, and that to attempt some other system could not possibly make it worse.

Duff gave them the privilege of examining the senior class in his college, which had been under his care for nearly four years. This examination was made without the class having received any intimation that it was coming. Taking them into a private room, the examination was conducted by the Apothecary-General, as follows:

He asked, "You have got many sacred books, have you not?" "O yes," was the reply; "we have many Shastas, believed to be of divine authority. Some are very old, and others have been written by Rishis (holy sages) inspired by the gods." "Have you not also Medical Shastas, which profess to teach everything connected with the healing art?" "O yes," they said, "but these are in the keeping of the Bhoido, or physician caste; none of us belong to that caste, so that we do not know much about them." "Do you doctors learn or practise what we call anatomy, or the examination of the human body with a view to ascertain its real structure, in order skillfully to

treat wounds, bruises, fractures, etc.?" "We have heard them say that anatomy is taught in the Shastas, but it cannot be like your anatomy," "Why not?" "Because respectable Hindoos are forbidden by imperative rules of caste to touch a dead body for any purpose whatever; so that from the examination of the dead body, our doctors can learn nothing about the real structure of the human body."

"Whence then have you got the anatomy which, you say is, in the Shastas?" "They have got it out of their own brains, though the belief is that this strange Shasta anatomy must be true or correct, it being revealed by the gods; but we now look on this as nonsense." "What, then," said the Commissioner, "if the Government should propose to establish a medical college for Hindoos under European doctors, like the medical colleges of Europe; would you approve or disapprove of such a measure, or how would it be viewed by the natives generally?" "We, certainly, who have been taught European knowledge through the medium of English, would cordially approve; but our ignorant orthodox countrymen would as certainly disapprove." "Well then, were a college of this kind established, would any of you be disposed to attend it; or would there be insuperable objections in your minds against your doing so?" "Not at all," they said; "if we were not already otherwise committed to some course of life which would prevent us, we should be very glad to attend." "What," said the commissioner, "would you actually be prepared to touch a dead body for the study of anatomy?" "Most certainly," said the head youth of the class, who was a Brahman; "I, for one, would have no scruples in the matter. It is all prejudice, old stupid prejudice of caste, of which I at least have got rid." The balance of the class acknowledged these as their sentiments also.

The committee were highly pleased with this examination, and the result after much controversy was that in an order dated 28th January, 1835, the old college was abolished and a new one created, under the Committee of Education, "for the instruction of a certain number of youths in the various branches of medical science."

This college was open to all who could read and write the English language in addition to their own. The college was opened June 1, 1835, under European professors whose names were as follows: Dr. Bramley, the first principal, who died soon after; Dr. Henry Goodeve; Dr. Wallich, the Danish botanist; Dr. O'Shaughnessy, the Irish professor of chemistry, and two others whose names are not given. David Hare was secretary.

Duff's enthusiasm was not greater than the grand results under the management of this committee, who aimed to have an institution, "ample, comprehensive, and worthy of a great government; not intended merely to supply the wants of the State, but of the people, and to become a moral engine of great utility and power."

The time came after the first six months of study for the first dissection. Great interest was manifested as to how Duff's students would acquit themselves. But Modosoodun Yoopta, of the Bhoido, or physician caste, was the first to wield the knife, and cut not only the dead body which lay before him, but the fetters of caste and superstition that had bound them from the time *Susruta* wrote his anatomical dissertation, nearly three thousand years before. *Rajendranath Mitter* followed, and one after another of the class, until they were all engaged.

The historian states that the number of subjects supplied for the dissecting tables in 1837 was sixty, and that in 1844 they had arisen to above five hundred, and he adds, "and now must be five times greater." Duff's students took the highest honors in the medical faculty in the University of Calcutta, and one of them is a professor in the medical college. In other places medical colleges soon sprang up, at Bombay, Madras, Lahore and Agra, and what that single sentence of Duff's, "only use English as the medium, and you will break the backbone of caste," has accomplished for suffering humanity, if it could be recorded, would form a grand chapter in the history of the world's progress.

The Arcot mission was established in 1855 by the three

BROTHERS SCUDDER,

who were not only preachers, but physicians. They not only established a large number of schools in the district in which they labored, but in 1866 they established a medical hospital. *Ex-Secretary Seward*, when on his trip around the world, in 1870, visited this mission. He reported that the year prior to his visit, "fifty-three thousand nine hundred and sixty-three patients had been treated from its dispensary, and that "seven hundred and fifty-three of these were indoor patients, who were provided with beds, food, and clothing." He awards to these gentlemen the highest meed of praise for their self-denying labor, and adds, "That beyond a doubt, the success of this mission is due to the persevering energy and winning address of these preachers; but it was more to their happy combination of medical practice with their religious teachings."

India, through the protection and assistance of

the government, is becoming rapidly permeated with medical knowledge derived from western nations. The *Zenana* caste, however, remains unbroken; but Christian philanthropy can solve this question also—how, in what manner, and by whom, will be reserved for another article.

A CASE OF DISLOCATION OF THE WRIST.

BY JOSEPH B. POTSDAMER, M. D.,

Resident Physician of the Jewish Hospital, Philadelphia, Penna.

After reading the various authorities, one would almost come to the conclusion that dislocations of the wrist were exceedingly rare or even impossible. The great objection raised to the diagnosis of this affection, is that fractures at the wrist are mistaken for dislocations.

As so few well authenticated cases of this form of dislocation have been placed upon record, I have been led to publish the notes of the following one:

James Carraugh, aged eleven, a native of Ireland, was brought to the Jewish Hospital on July 7, 1882, at 1:45 p. m., a half hour after the accident. The history was as follows: After dinner, he climbed a tree, and whilst sitting on a limb it broke, precipitating him a distance of about twenty feet. Recovering from the momentary shock, he found his left wrist painful and swollen, and was unable to move his hand.

Upon examination, I found the above conditions existing. What he considered swelling was really a deformity caused by the carpal bones being pushed backward and upon the bones of the forearm. The deformity was uniform throughout, not greater on any one side. It resembled the case of dislocation of the wrist depicted in "*Agnew's Principles and Practice of Surgery*," Vol. II., page 19, Fig. 958, excepting that the deformity was more marked.

I placed the patient under ether. Then grasping his hand with my left, and his fore-arm with my right hand, and my thumbs over the joint, I at once reduced the dislocation by extension, counter-extension, and pressure over the joint. He had lead-water and laudanum applied to the part for the two succeeding days. No bandage or splint was used until the seventh day, when, after having consulted various authorities on the subject, I concluded it might be best to apply a splint. After two days, there being no pain, swelling, or the slightest deformity about the joint, I removed the splint.

Bearing in mind that a fracture might manifest itself later, the patient was kept under observation until the 28th of the month, three weeks

after the accident. After his discharge, I had him come to visit me every day for the three succeeding weeks. In all this time, no symptom of a fracture could be detected, and there was always perfect motion in the joint. I saw the boy as late as the 11th of November, and his left wrist is as perfect as his right.

I am positive this was a case of simple backward dislocation of the wrist.

METHODS OF OVERCOMING RIGIDITY OF THE OS UTERI.—HOW NOT TO USE ERGOT.

BY BOARDMAN REED, M. D.,

of Atlantic City, N. J.

President of the Atlantic County Medical Society; Physician to the Seaside House for Invalid Women.

Doubtless a great deal of mischief sometimes results from "meddlesome midwifery," and nature alone is in many cases better to be trusted than any disturbing efforts of the accoucheur. Yet nature often fails entirely when a little timely and skillful assistance ensures a safe delivery. In my experience the most common cause of tedious labor is a rigid *os uteri*, and according to the same experience no obstacle is usually so easily overcome by a judicious interference.

In the earlier years of my practice I once gave ergot in a case of abortion at the fifth month, when labor was being retarded by this cause. I had been well instructed, and, therefore, knew that ergot was wholly unsuitable whenever such an obstacle to speedy delivery existed, but mistook the real condition, from a lack of the *tactus eruditus*. The ergot brought on pains of tremendous force, and, as is to be expected from its physiological action, contracted the circular muscular fibres in the *os* more than those in the fundus, so that the hard, thin, unyielding rim which the finger encountered was unmistakable for one of even very moderate experience. I tried applying extract of belladonna to the *os* locally, and might as well have rubbed on lard for all the good resulting. Then hot water, that modern cure-all, was faithfully injected into the vagina, but without any decided effect. My patient was screaming from the intensity of pains which were literally doing no good, but much harm, by the constant impact of the hard head against the scarcely more yielding fibres of the *os*. The great value of the various narcotics in such emergencies had not then been impressed upon me by the lessons of experience; but the situation was becoming desperate, and something had to be done. The relaxing power of the warm bath occurred to me and I ordered a tub of hot water to be brought in. The patient was then taken out of bed, and made to sit in this tub, thus receiving a hot hip

bath. In fifteen minutes, or even less, after she got out of the tub, the *os* had freely dilated, and almost immediately thereafter the fetus was born.

I have never had to repeat this experiment with the hot bath, for since then I have never given ergot, if at all, until after the *os* had fully dilated, and have learned that by administering chloral and opium, by the mouth, or preferably, morphia and atropia hypodermically, the most refractory *os* can be speedily relaxed. A sleep of half an hour or an hour, however procured, rarely fails to accomplish the desired result. But very often when the intention has been to procure such a nap for its dilating power, the effect of the narcotic has been to soften the *os* at once, and thus to render the pains more efficient, without any sleep ensuing, so that the patient and her friends would charge me with having administered "forcing medicine," instead of an anodyne.

In some cases very good results have been produced by having the patient sit over a commode filled with hot water, the steam acting as a relaxing agent. This is sometimes highly useful when labor is delayed by a rigid *os*, and besides has an excellent moral effect upon the fussy friends, who are never contented unless something is constantly being done.

Scores of cases could be reported if necessary, where the above-mentioned measures have proved promptly efficacious, in some instances after the woman had been having severe pains for from twelve to twenty hours previously without making any progress; but it seems useless to narrate them in detail.

There appears however to be reason enough for calling attention very strongly to the fact that ergot is above all drugs dangerous when there is rigidity of the *os uteri* during parturition, and that chloral, morphia and atropia (the last two hypodermically by preference) are the most valuable relaxing agents in such a condition. I notice in the *Reporter* of December 16th, p. 697, the report of a "Death During Parturition," which has suggested to me the importance of discussing this subject. The attendant in that case not only gave ergot and apparently "pushed" it in a case of rigid *os*, but attempted to perform version under the same unfavorable condition, and that too for no better reason than that he "found the left hand by the side of vertex engaging the small unyielding *os*." Those were, of course, errors of judgment which, happening under such exciting and embarrassing circumstances, do not call for harsh criticism. But they show at least that the profession has not yet all learned how rightly to use that two-edged sword—ergot.

HOSPITAL REPORTS.

STATE HOSPITAL, PRAGUE.

BY PROF. A. PRIBRAM,

Professor of Practice of Medicine, University of Prague.

Translated by LOUIS SCHWARZ, M. D., for the MEDICAL AND SURGICAL REPORTER.

Diabetes Mellitus.

NOVEMBER, 1882.

GENTLEMEN: If you approach the bed of this very ill man, D. A., age 63, butcher by trade, the first thing that will attract your attention is a peculiar odor, slightly resembling chloroform, which comes from the patient's breath. The urine has the same odor, and if we test it with Sol. Ferri Chlor., without heat, we obtain a beautiful brownish red color, due to a substance called *acetessig-äther* or acetate of acetic ether, also aethyldiacet-saure or diacetic acid ethyl, whose formula is $\text{CH}_3\text{CO}\cdot\text{CH}_2\cdot\text{CO}\cdot\text{O}\cdot\text{C}_2\text{H}_5$, or $\text{C}_6\text{H}_{10}\text{O}_3$, which often occurs in diabetic urine, but is often found in urine where sugar does not exist. This substance is generally found in connection with an increased amount of acetone; this has been proved by my assistant Dr. Jähksch. Care must be taken not to confound this substance, acetic ether, with salicylic acid, because salicylic acid gives a similar color with Sol. Ferri Chlor., as do also other aromatics. This can be proven by applying heat; if you take a quantity of urine which you suppose contains acetic ether, and heat it, and then add Sol. Ferri Chlor., you will not obtain any red color, or very little, as the acetic ether is driven off by the heat; but if you apply the same test to urine containing salicylic acid, the color remains, as heat does not drive off salicylic acid. Another method is by extracting the acetic ether with pure ether, and allowing it to remain for a few days, when the red color disappears; whereas with salicylic acid it remains. The urine of this patient is scanty, and contains between four and five per cent. of sugar, sp. grav. 10.30, slight trace of albumen, no renal casts. The patient is comatose, not being able to reply rationally when spoken to, only murmuring a few words and then sinking into a sleep. Respiration slow, deep, stertorous. He was transferred to us from the surgical clinic, where he entered in consequence of gangrene of the foot. The only information received from him was that after a long walk he noticed a slight excoriation on one of his toes, which was caused by a tight boot; it then developed into an ulcer and afterwards became gangrenous. This is then a case of diabetes mellitus with gangrene of the right lower extremity. We also find sugar in the urine of patients suffering from carbonic acid and strychnia poisoning, sciatica, and in mothers who nurse children from the breast; these are only symptoms, and not diabetes mellitus. The cause of the gangrene may come from weakened heart action, as in severe cases of typhoid fever and other exhausting diseases; this is not the case here, as we can feel a strong pulse in the radial and femoral arteries, also a normal sound is heard in the femoral artery; it could also be due to an embolus of one of the lower branches of the femoral, or a local extravasation due to atheromatous disease, and in consequence the gangrene; this is not the case here,

as is proved by the extent of the gangrene, which is not limited to a part supplied by a certain artery, but is irregularly diffused over several toes, the dorsum pedis, both malleoli, and with abscesses. Often we see in diabetic patients gangrene developing from slight injuries; this liability to gangrene may be accounted for by grape-sugar and its products in the tissue. My personal idea is that a tissue containing sugar affords better conditions for the propagation of septic germs; indeed, if we place such a patient with gangrene on a diabetic diet, we sometimes find the gangrenous process abating, a line of demarcation forming with the sugar disappearing in the urine. I observed this in a medical gentleman some years ago, the gangrene abating when the sugar disappeared in the urine; the gangrenous parts were amputated with good results, and he lived for more than a year, and finally died of the disease. This patient cannot be placed on a diabetic diet, as he is already comatose; if we withhold from such patients all carbo-hydrogenous substances they continue to pass large quantities of sugar, which is produced by the decomposition of the albumen of their own bodily tissues. Prof. Ebstein, of Göttingen, has proved that with sudden introduction of a diabetic diet, the above described acetic ether can occur in the urine, and coma may follow. The best plan of treatment in this case will be a full, nourishing diet, as beef-tea, red wine, solution of pancreatic beef, small quantities of arrow-root, fresh air, large quantities of water to promote renal secretion and drain off foreign matter. The prognosis is bad, as the patient has diabetic coma and will die shortly.

The narcotic producing this coma is known (acetic ether), yet we have no agent to prevent its deadly action; the discovery of the substance was the first step towards elucidation, and we hope before long to obtain means of annihilating its effects and prevent its production. There are as many causes for this disease as there are authors who have written on it, some without anatomical lesions, others from brain tumors especially of the fourth ventricle, alterations of the solar plexus, liver and pancreas. As yet we have no signs for an anatomical lesion in this case. Patient died in two days, post mortem revealed an extensive atrophy of the pancreas. A great quantity of pus is to be seen on the tongue of this patient, due to a peristaltic abscess of the upper maxilla. Caries of the teeth and alterations of the gums and maxilla are often found in this disease; they may be considered symptoms of diabetes mellitus; when they are present it is necessary to examine the urine—this may aid to a correct diagnosis. You can also see an eczema of the glans penis and prepuce of parasitic origin, as has been proven by a microscopic examination; this is due to the diabetic urine passing over these parts; this eczema often may lead to the discovery of the disease.

Case II. J. S. age 45, type setter. About a year ago patient noticed himself having great thirst and drank water freely; had to pass urine quite often; found himself becoming weak and unfit for work, but no other symptoms. Patient now passes twelve pints of urine in twenty-four hours, containing six per cent. of sugar; slightly emaciated, with dental caries and abscesses of the gums; with these exceptions no other pathological symp-

toms are to be observed. Patient has been placed on a mixed diet for the purpose of testing several remedies; by restricting his diet the sugar does not diminish. This is known in the literature as a grave case. I have used salicylic acid without success; I then used iodoform, which has recently come to us from Italy. The iodoform is placed in a bottle with tonca beans, and in this way the disagreeable odor is prevented; it is then given in pill form 10 cm. or 2 grs. four times daily. This patient has received the iodoform for the last two weeks, the remedy is well borne by the stomach; the decrease in sugar has not been great, only from 250 grms. to 196, a decrease of 54 grms. or nearly two ounces; the weight of the body has increased two pounds. I cannot recommend this remedy yet, though it is worth a trial.

Finding the iodoform of no great value, it was discontinued and morphia in .005 or 1-10 grs. dose, in the evening substituted for it, and the mixed diet was continued. The result was more favorable, the quantity of urine decreased to six pints daily, and a diminution of sugar to 165 grms. instead of 250; the percentage of sugar decreased to $4\frac{1}{2}$ p. c., the body weight gained three pounds. This remedy was discontinued and potass. brom. in 15 gr. doses three times daily substituted: this was used for seven days without any result, and the morphia was again used. The best results were obtained from the morphia and iodoform. The remedy employed most is the Carlsbad cure; in light cases we see great benefit from this mode of treatment, the sugar sometimes disappearing during the treatment and remaining absent for a number of years; in other cases, the severe ones, we find no effect and the patient loses a great amount of flesh. The Carlsbad method is more effective at the original spring than by drinking the bottled water: this may be due to a compulsory strictly diabetic diet, and secondly to the muscular exercise in the long walks the patients are required to make at the springs between the intervals of drinking the water. I believe that in light cases of this disease long walks and gymnastics, as with dumb-bells etc., will be beneficial, as we know the muscular tissue contains glycogen, and if we as it were burn this substance by exercise and gymnastics, we prevent it being absorbed and converted into sugar. As I think the cure depends mostly on the diet, I will make a few remarks in regard to it. Diabetic patients have great hunger, due to the periphery of the vagus nerve being irritated by the sugar. Therefore you must not place your patient on a restricted diet, but rather on a full diet. All sugar and starchy articles must be avoided; such articles may be given, as beef-tea, sol. pancreatic beef, eggs, fish, cheese, oysters, some vegetables, red wine, Burgundy, sherry, small amount of bread, but what is better Graham's bread, and tea from a species of chamomile; tea or coffee sweetened with manna-sugar; the only objection to mannite is its cost. If the great amount of urine passed is due to an irritation of the kidney from the sugar, this may be relieved by a narcotic at bed-time. Other remedies are used, as carbolic, salicylic, lactic acids, arsenic, ergot; but these remedies as well as iodoform must not be given to anæmic patients; and if they do not agree with the stomach they must be immediately abandoned.

If Carlsbad water or other alkaline waters are

not to be obtained, you may give the plain salts, as carbonate, sulphate, nitrate, chloride of potassium or sodium in 3 ss. doses four times daily.

BELLEVUE MEDICAL COLLEGE, NEW YORK.

CLINIC OF DR. LEWIS A. SAYRE.

Talipes Equino-Valgus and Equino-Varus.

W. E., aged 3 years. This little fellow was brought here last winter to the clinic, and was at that time suffering from talipes, the feet being crossed upon each other, never having been able to stand; the child was also suffering from congenital phymosis, the prepuce being closely adherent; I then decided to preform the operation for phymosis only, and note the result, if any, upon the deformity. You now observe that the feet are apart, but the equinus is strongly marked, and that the toes only touch the floor, and now you observe that the right foot is equino-valgus and the left equino-varus: the contraction of the gastrocnemii muscles in this case is so strong that the tibia is actually bowed forward; now, by flexing the knee, we can lengthen these muscles, and the feet can then be brought almost to a right angle with the tibia; but upon point pressure being made upon the tendo achillis when placed upon the stretcher, you observe that a spasm is instantly produced.

Now, upon extending the leg, we instantly notice the deformity of the foot again, and with the leg in this position no amount of force can flex the foot.

The spasm which you have observed plainly indicates that these tissues have undergone structural change, and cannot, under any circumstances, be stretched any further, and that the muscles have become what I term contractured.

A contracted tendon is one which is shortened but is capable of being elongated by constant traction upon it; but when you have stretched it to its utmost and yet cannot secure the normal length of the muscle, if upon pressure being made upon it while held in that position a spasm of the muscle be secured, you may be sure it has undergone the change of structural shortening, that the fibrillæ of the tissues have become adherent to each other, and therefore further extension is impossible; then you will require to use the tenotome. This is very important for you to understand. If I could gradually bring the foot around to the normal position and it gave no reflex spasm, I should not think of section. I now as you observe take a piece of light board, cutting it the width of the foot and allowing it to extend a little beyond the toes; I then take a long strip of adhesive plaster, which passes around the back part of the board; we then take a broad strip passing it from the anterior end along the under surface, bringing it over the upper surface to the point started from, placing under this a padding of cotton; two lateral straps are then formed, and the whole secured with a roller; your foot piece is then ready for application.

In this case the plantar fascia does not need section, there is no reflex spasm given at that point; both tendo achilles will require cutting. I now take this tenotome, which you will observe is curved and round-pointed, and making a slight

puncture pass the blade in a flat position under the tendon and fascia, then turning the edge upon the tendon with a short sawing motion, at the same time pressing the tissues down upon the blade, the tendon is completely severed, as can be heard with a distinct snap; I then instantly turn the instrument upon its flat surface and withdraw it, at same time placing my thumb upon the wound to prevent the entrance of air, and we now closely seal the wound with a strip of adhesive plaster. The foot is now brought at once to the normal position, which you observe can now be readily done with the leg in the extended position; the foot board is now applied, bringing the posterior strap across the instep, and the lateral straps across the foot directly; we now secure this firmly with a roller bandage, and then pass the broad anterior strap from the toes up the leg, which retains the foot at a right angle; we continue the roller up the leg, and in this case, as the child is small, will pass it up to the thigh, in order to secure greater security of our dressing. The right foot being slightly everted, a guy is now placed upon the inner part of the foot and passed up the leg, and in this manner secured in the normal position. The left foot was operated upon in precisely the same manner, but the foot in this case being slightly inverted, the guy was placed upon the outer portion of the foot, upon the same principle as previously mentioned. This dressing will not be disturbed for ten or twelve days; you will, however, observe that the toes are left exposed in order that you may ascertain if circulation has been interrupted; if you at any time observe the circulation has been arrested, remove your bandage at once, and reapply it in such a manner as to admit of free circulation.

I wish to thoroughly impress upon you the necessity of attending to all details, as I have found in several cases that my treatment has not been carried out successfully, simply because these details have been neglected.

[Condition of the patient as brought before the class two weeks after the operation.]

In this case there was no functional disturbance following the operation; and by this time union should have taken place between the severed ends of these muscles [dressing was now removed]. You will here observe that the wounds are completely healed and by irritation of the muscles slight extension of the foot can be secured, showing that the union has been perfect; friction and electricity must now be applied to the parts, in order to secure vitality to the same.

You have now seen the operation for the relief of club-foot in all of its different varieties, the principle being simple division of the contracted tendons, after which the foot is to be *at once placed in its normal position* and there secured; the after treatment consisting in what I have but recently stated.

Many authors of the present day are adopting the plan of treatment which I advise; previously they have been in the habit of securing the limb in the deformed position after the operation; when the wound has become perfectly healed, gradual traction is made upon the new material thrown out from the severed ends of the tendons, in order to restore the foot to its normal position. But the pain induced by that method was so intense that

it had to be interrupted, sloughing in many instances resulting from this treatment and calling for the constant attention on the part of the surgeon; the results being also exceedingly unsatisfactory; whereas, by bringing the foot into the normal position immediately after the operation, the exudate is sufficient to fill up the space between the severed tendon, and air being excluded organization takes place; should you allow any air to pass into the wound suppuration may occur.

You have seen me perform the most simple method of treatment in this case, and are now capable of forming an opinion upon the subject; the main point, however, is that while securing the foot in the normal position, you do not obstruct the circulation.

In some cases it is necessary to cut the integument itself; in some instances I have made a clean section of the plantar fascia and integument when it also has become contracted; this however is very rare. The simple division of the tendons and restoring the foot to the normal position, does not however end the treatment; an important part is for you to vitalize the partially paralyzed muscles, and until you have effected this you have not cured club-foot. To all appearances this child is cured of club-foot, but he has not yet the power to move the foot as it should be moved; and it may require some few months' persistent treatment in order to thoroughly revitalize these muscles. In some cases it is necessary to use artificial aid to assist these muscles; in such cases I advise the shoe devised by Mr. Hudson, to which are attached small rubber bands, so arranged as to guide the foot in the desired position according to the deformity to be cured. These slight aids are of the greatest importance to you in restoring the parts to their normal position, and if you neglect to use this while the child is recovering, a relapse may occur and you may do yourself an injury by performing the operation, whereas had you carefully followed up the indications your treatment would have proved most successful; if you are deprived of the services of the instrument maker, we have an excellent substitute for the Hudson shoe in Mr. Barnell's dressing. A slight guide even when the child is going barefoot will often accomplish the desired result. If the foot can only be brought out, the weight of the body itself will often overcome the action of the peroneal muscles. It is however to be remembered that in the application of these artificial muscles, they must not be applied so strongly as to prevent the patient from putting the foot in the deformed position if he desires to do so. The application of these artificial muscles is equally applicable to deformities of other parts of the body.

MEDICAL SOCIETIES.

NORTHERN MEDICAL ASSOCIATION OF PHILADELPHIA, NOVEMBER 24, 1882.

Placenta Prævia.

Dr. Daniel Longaker narrated the following: Mrs. X. presented the early signs of pregnancy as instanced especially by cessation of the catamenia. At the fourth month, however, she was surprised at a return of the menses, which occurred from

that time until labor with irregularity. When labor began, hemorrhage occurred, and became more profuse with the accession of the pains. Several large clots were voided, and the dilatation seemed incapable of being effected. Investigation revealed the placenta prævia. The extent of hemorrhage and consequent condition of the patient rendered prompt relief a necessity, especially as the fetal heart sounds still were present, and a possibility of delivering a living child probable. An ineffectual attempt to use the forceps was made and was followed by version. When the breech was partially delivered, prolapse of the funis occurred. The compression of the cord resulted in obstruction to the circulation and death of child. The after-coming head occasioned considerable difficulty, and would not engage. This was due to extension, which was subsequently demonstrated to depend upon the fact that the child had been delivered through the centre of the placenta, which latter mechanically interfered with the proper movements of the head incident to engagement. This complication was successfully met by applying the forceps to the after-coming head. Considerable collapse occurred, but reaction was eventually established. The collapse was due to the manipulation in part and largely to the hemorrhage, which during delivery was augmented. In reply to a question, Dr. L. stated that considerable difficulty was experienced in adjusting the forceps to the head.

Dr. E. R. Stone related the history of a case of partial placenta prævia, in which in due time the placenta separated and the hemorrhage ceased. The presenting head engaged, and delivery was effected without any untoward symptom. In another case of partial placenta prævia he detached the circumference (lesser) of the placenta, and applied the forceps to the head with the result of delivering a living child. In a case of total placenta prævia, the prominent symptom of hemorrhage occurred in the beginning of labor. As the os was not dilated and the loss of blood great, a tampon was employed. After the vagina was thoroughly packed and retained by a T-bandage, the patient was carefully watched. In about three hours intense bearing down efforts developed, resulting in extrusion of the tampon. No hemorrhage followed removal of tampon, and the fetus, which was small (seven months), was found to occupy the vagina. The placenta had preceded the fetus, which was contained within the unruptured membrane. Recovery was excellent. This case serves as an argument in favor of the use of the tampon. If the membranes have not been ruptured, it is not very probable that the dreaded internal or concealed hemorrhage will occur. When version is resorted to, the profession appear to entertain too great a dread of making strong traction on the body to deliver the after-coming head. Much more force can be applied to the body than is generally admitted without danger of producing luxation of the vertebra.

Dr. Robt. Hess had seen but one case of placenta prævia, and it was of the partial type. No hemorrhage had occurred throughout gestation, a point frequently noticed in the partial placenta prævia, and one of diagnostic importance. The treatment here instituted was separation of placenta at its lesser attachments, application of forceps, and delivery. The result was favorable to

mother and child. In complete prævia the tampon is certainly demanded, for it effectually closes the gaping and torn placental sinuses from the distal surface, while the presenting portion of the child exerts a counter-pressure on the proximæ, whereby the hemorrhage is reduced to the minimum. The doctor also urged upon the society the importance of prolonged and persistent efforts at resuscitation of apparently asphyxiated children. In his case, after assiduous effort for half an hour, he was rewarded by the establishment of respiration and life. Many of the adjudged cases of still-birth may by perseverance be restored and life secured.

Meeting of December 8, 1882.

Dr. J. Solis Cohen reviewed the recent method of treatment employed by the Germans in acute articular rheumatism. The statistics made such a favorable impression that he determined to employ the means when opportunity presented. At the German Hospital a man was admitted to the ward suffering with a frank attack of acute articular rheumatism. The joints were swollen, red, hot, and exquisitely painful, temperature hyperpyrexial, endocardial murmur present. According to the method referred to, a fly-blister 4x4 inches was applied over the cardiac region. No other treatment was instituted. In the course of twenty-four hours marked relief followed. Convalescence rapidly supervened, and in four days no evidences of the attack remained. In three other cases the same brilliant results followed.

Dr. J. T. Eskridge has employed the blister in one instance with the above result. He also referred to the use of essential oil of Gaultheria, which is said to contain as its active principle salicylate of sodium, or a something that acts identically with it.

Dr. H. Rihl has employed the blister and obtained very beneficial results.

Dr. Cohen mentioned the fact that in the typhoid fever wards of the German Hospital an unusually large number of instances of septicæmia have occurred during the course of the fever. It manifests itself in the formation of numerous small abscesses. One case of unusual interest is that in which an abscess developed over the sternum. After its evacuation, the introduction of the probe revealed the fact that the periosteum had been destroyed, and that caries sterni had developed. The caries progressed until a portion of the bone was separated and the mediastinum opened. Respiration occasioned a bulging outward of tissue through the perforation. This opening was artificially closed and cleansed once daily with disinfected washes, and the pus thoroughly removed. The purulent secretion diminished in course of time, and patient recovered.

Dr. J. T. Eskridge related an account of an Irish woman who had been struck on the sternum by her husband. Some time after she was attacked with typhoid fever. During convalescence an abscess, episternal, developed, and the patient died. Autopsy revealed an eroded periosteum and caries sterni. The destruction of the sternum in Dr. Cohen's case was so extensive that the pulsation of the right auricle was clearly seen, and the small loose piece of bone situated over the heart protruded by each expansion.

Dr. E. W. Holmes reported a case of puerperal eclampsia, interesting on account of the late hour at which after delivery the disease developed. The patient was a colored woman. The child was delivered about half an hour before the doctor arrived. He removed the placenta, and could detect nothing wrong except that the pulse was *abnormally slow*. The patient did not complain, and expressed herself as feeling very comfortable. The doctor remained about one hour and then left. The pulse was then 50 per minute. Eight hours after the accouchement a convulsion occurred and a physician near at hand was summoned, who left a prescription of "chloral and bromide." He did not administer the remedy, but left directions how to be given. The doctor was sent for, and arrived in time to see the third convulsion. The inability to swallow had not permitted the attendants to administer the remedy prescribed by the doctor, so the patient was practically without treatment all this time. Dr. Holmes immediately administered chloroform, but with no effect. Phlebotomy was then resorted to, and chloral and bromide of potassium administered per rectum. Morphine sulphas was employed also, hypodermically. The convulsions did not recur, but the coma which had developed did not yield, and death terminated the case. The case had not been before seen, and the renal secretion not examined.

Dr. H. Rihl delivered an Irish woman of twins. The labor was uncomplicated with the exception of a *throbbing* headache, which, however, passed off before the termination of labor. The doctor left the patient apparently in an excellent condition. On the following day when making his call he was informed that the lady had lain in convulsions the whole night. He found profound coma, which did not yield to remedies. The patient died the following day. In another case whom he had attended previously on several occasions, eclampsia occurred about half an hour after delivery. The convulsions occurred with varying frequency and severity for three days, and gradually disappeared. Recovery followed. He has noticed that the "after pains" seem to aggravate the convulsions.

Dr. J. G. Heilman attended a lady whom he delivered at 8 a. m.; at 4 p. m. convulsions developed. Potassium bromide was administered, and although unconsciousness continued for twenty-four hours, recovery followed.

Dr. Daniel Longaker met with one instance where during the second stage of labor eclampsia supervened. There were no premonitory symptoms noticed. Phlebotomy was immediately resorted to and f. $\frac{3}{4}$ x. of blood abstracted. In addition, free catharsis was induced by the exhibition of pulv. jalapæ comp. Bromide of potassium with full doses of morphia were also administered. Coma developed immediately after the first convulsion, and continued uninterruptedly, being complicated with occasional convulsions until death terminated the case on the third day. In this case albuminuria existed in a marked degree. When the circulation is failing in this disease, if remedies be employed to stimulate the heart it is essential that they be administered hypodermically, as the gastric functions are not active and absorption not to be expected.

Dr. J. G. Eskridge is of opinion that autopsies will elucidate the aetiology greatly. The view

that morbid conditions of the urine are causes, is undoubtedly true to a certain extent; but other pathological conditions, as embolism and thrombus of the cerebral vessels, certainly contribute to the development of the disease. Where effusion into the brain structures has occurred, bleeding is indicated; but if thrombus or embolism is present, such procedure is futile and injurious.

Dr. E. W. Holmes possesses great confidence in venesection and while an interne of Blockley Hospital saw several instances of recovery following this plan of treatment.

Dr. Henry Beates had met but two instances of puerperal eclampsia. In one, the lady's ninth confinement, there was a preëxisting albuminuria and epithelial casts, characteristic of desquamative nephritis. When labor began, the pains were ineffectual and teasing. They occurred at short intervals, but were unaccompanied with dilatation. Flatulence and nausea occurred; the former proving exceedingly annoying. About eight hours after the onset of labor, no dilatation being effected, a peculiar cephalic throbbing was complained of, which increased in intensity, but was *unaccompanied* with pain. This condition continued for little over an hour, when severe pain developed; and it was but little more than half an hour when, with a peculiar expression of face, and strange cry, a general clonic convulsion developed. After this passed over, in about ten minutes a semi-comatose state remained. The convulsions returned in about one hour, and occurred with varying frequency during the following four hours. The distension of the frontal, temporal, facial and cervical veins was extreme during the paroxysms. Prior to the first convulsion, the pulse assumed that peculiarly slow, full, throbbing character, so significant of the second stage of opium poisoning. During the paroxysms it became rapid, and in the interim reassumed its slow, full, bounding character. Croton oil was promptly administered, also the routine mixture of chloral and bromide; ether was used to mitigate the severity of the convulsions. The then much-extolled drug pilocarpin was used hypodermically, and profuse diaphoresis promoted in obedience to the uræmic theory, and the possible increase of elimination through the perspiration of five per cent. of this poison. The convulsions and evidences of cerebral hyperæmia continued, however, unabated; phlebotomy was then resorted to, and f. $\frac{3}{4}$ xij. according to "book directions" abstracted. This did not stop, but only ameliorated the severity of the convulsion. The vein was reopened and the blood allowed to flow until the *pulse gave evidence of its effect*. Following this no convulsions returned, and recovery in due time was established. In case No. II., the eclampsia developed during the first stage of labor. Phlebotomy *for effect*, not conventional quantity of blood, was promptly instituted. The convulsions immediately ceased; dilatation and delivery spontaneously occurred in this as in case No. I. Recovery was excellent.

In reference to the rational treatment nothing is definitely known. We only theorize as follows: Uræmia exists, and is due to the structural renal lesion. This poison determines a hyperæmia of the brain, and engenders cerebral convulsions. Phlebotomy will relieve the hyperæmia, to say nothing of the removal of the *materies morbi*, which is accomplished, how we do not know, and the

cases recover. *Early* bleeding must be resorted to, before irreparable damage has been done by the extreme hyperæmia and consequent effusion. If the convulsions are dependent upon embolism, and especially thrombus, premonitory symptoms will certainly manifest themselves.

Dr. Beates also reported a case of tetanus due to eruption of a fourth wisdom tooth. The eruption of the preceding three teeth was unaccompanied by similar manifestations. The patient is a gentleman, twenty-five years of age. On last Friday morning the gum tissue became swollen and extremely painful. The swelling increased, and involved the substance of the cheek. On Saturday rigors and fever developed, accompanied by rigidity of the masseters and general pains. This was not regarded as serious by the family until Sunday, when a severe rigor, followed by high fever and clonic spasms, supervened. I first saw him that evening and found the following condition: Trismus marked; absolute immobility of inferior maxilla; temperature 104° ; rigidity of trapezii and sterno cleido mastoidei; risus sardonius and corrugation of the corrugator supercilii. The anterior belly of the occipito frontalis was also thrown into transverse folds. The femoral flexors would stiffen on attempted movement, and contact and noises occasioned opisthotonos. Darting acute pains situated in spinal cord were greatly complained of, and dyspnea due to spasmus incident to attempts at deglutition.

Having had three cases previously, all of which proved fatal, and calling to mind the physiological action of the remedies so universally administered in this terrible disease, and remembering that tetanus is pre-eminently a disease due to disintegration and depressed action of the spinal centres, I determined to exhibit the most powerful spinal excitant known. Consequently strychnia sulphatis was given in $\frac{1}{20}$ gr. doses every two hours, and its effect carefully watched. After the first few doses its effects were manifest, and it was deemed requisite to increase the intervals of administration. One every three hours was ordered. The disease remained in statu quo for four days, when the opisthotonos became less severe and less frequent. Convalescence was fully established in the course of nine days, and now the patient is well advanced toward recovery. Stillé mentions eight cases of tetanus, including traumatic and idiopathic, in which strychnia was employed from the beginning. All of these recovered, and this instance is reported with the hope of inducing further trials to be made.

Dr. James Collins reported a case of traumatic tetanus, which he treated successfully by maintaining a constant condition of tæxæmia with cannabis indica. In another case, that of a physician who was suffering from successive crops of furuncle, there was developed a tetanoid condition. On the exterior surface of the forearm there appeared a sluggish inflammatory area, which was very painful, and seemed to avoid progressing to suppuration. This spot was very tender, and occasioned extreme suffering. Trismus developed, and all the manifestations of developing tetanus were present. The area was freely incised, and emollient poultices applied to encourage suppuration and elimination of pus. Free diaphoresis was induced by pulv. ipecacuanhe comp. and cannabis indica freely administered. Under this treatment

the symptoms gradually subsided, and the patient recovered. I often reflect and wonder if there is a condition that might be termed tetanoid, due to reflex irritation, which, if neglected, would develop this dire disease, which is amenable to treatment, or whether real tetanus is possible of cure.

TRANSACTIONS OF THE OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, December 7, 1882. Vice President, Dr. T. M. Drysdale, in the chair. Dr. R. P. Harris being called temporarily to the chair,

Dr. T. M. Drysdale reported a case of *uterine myo-fibroma* in a woman, aged 31. He described the case and subsequent operation at length.

Dr. B. F. Baer (in response to a call from the chair) inquired of Dr. Drysdale the effects of ammonium chloride and ergot, as administered by him in this class of cases. Does not ergot, when given during the menstrual flow, increase the quantity of the discharge? Does ammonium chloride have any effect in reducing the size of the tumor? He had used ammonium chloride a great deal, in fact he gives it in every case of uterine fibroid that comes under his care, but he has not seen or expected much from its employment; he considers it an alternative; it makes the patient feel better, but he has not seen any reduction in the size of the tumor follow its use; it relieves the painful flushings connected with the existence of a uterine fibroid or the menopause. He is not very sanguine as to the effects of ergot used in any way, hypodermically or otherwise. To reduce the size of a uterine tumor, and it certainly can effect nothing in the case of a pediculated subperitoneal, uterine fibroid.

As regards the hazard of the operation, under the conditions existing in the case narrated by Dr. Drysdale, it cannot be too strongly expressed; but there have been instances of recovery under conditions apparently as desperate as those just detailed.

The case referred to by Dr. Harris (Chairman *pro tem.*) was operated upon by Dr. Goodell. The patient was a lady of middle age, who had been suffering from profuse hemorrhage, which was endangering her life. This hemorrhage was the result of the existence of a large uterine tumor, and Dr. Goodell decided to attempt oöphorectomy as a means for her relief. An incision three or four inches in length was made in the middle line of the abdomen. The large size of the tumor made it very difficult to reach the ovaries. One was, however, reached, and successfully ligated and removed without causing hemorrhage, although the pampiniform plexus was very much enlarged. It was necessary, in order to reach the other ovary, to enlarge the abdominal incision and roll the tumor over. It was found and removed, but a large plexus of vessels was ruptured in the turning, and the hemorrhage was frightful, the blood escaping from both ends of the vessels: ligatures were passed through the substance of the tumor, and finally succeeded in stopping the loss of blood. The doctor thought he might be compelled to remove the entire uterus to stop the hemorrhage. This had happened to Knowlesy Thornton.

This patient recovered, but Dr. Baer had seen death from peritonitis result in similar cases from the exploratory incision alone, the tumor and ovaries being found to be in so vascular a condition that Dr. Goodell was afraid to complete the operation.

Dr. Harris remarked that he was present at this operation, and was a close observer. The veins were ruptured during turning of the tumor; there was a peculiar anastomosis of the large venous trunks at the point of rupture. In this case the tumor had formed no adhesions.

Dr. Harris had been present at an operation by Dr. W. W. Keen in a similar case. The tumor was smaller, but the hemorrhages had been so profuse before the operation as to leave the patient waxen in appearance. In this case the tubes were tied close to the uterus, and were removed with the ovaries.

Dr. Baer remarked that Dr. Goodell had been very successful in operating by removing the ovaries for the cure of metrorrhagia, the consequence of uterine fibroids.

Dr. Githens, in answer to the first query by Dr. Baer, remarked that though not successful in relieving menorrhagia by the infemal use of ergot, he had had very satisfactory results from the use of ergotine suppositories in cases in which there was no tumor present.

Dr. A. G. B. Hinkle alluded to several cases in which he had used ergot for the relief of menorrhagia, due to the presence of uterine fibroids, he had given it three days before the period, during and for three days after its close; he also gave ammonium chloride in ten grain doses, three times a day, all the time. This treatment had produced undoubted effects, and in some cases the tumors had disappeared.

Dr. Henry Beates had used ammonium chloride in the treatment of a lady who had a large uterine tumor. He continued it one year with marked effect. The menopause came on two years afterward, and the tumor has entirely disappeared.

Dr. Beates made some general remarks about the microscopical appearances in hard and soft uterine tumors, and thought that the effect of ergot would depend upon the presence or absence of muscular fibres as a component part of the tumor.

Dr. Drysdale, in closing the discussion, urged upon the members the desirability of limiting the operation of the removal of the uterine appendages for the cure of uterine fibroids to small tumors or to those in the early stage, and which have not commenced to undergo the softening process. He had noticed, in cases under his care, a small spot of softening begin in a previously hard tumor, and progress until the change was complete. The tumor presented this evening had undergone this change, and had undoubtedly assumed a malignant type. Before the operation it felt as if it contained a fluid. Since its removal it has shrunk to about one-half its original size from drainage of blood. From the description given during the debate, the tumor in the case of Dr. Goodell's differed from the one presented this evening in being much smaller, harder, and free from adhesions. The hemorrhage in his case came from a single laceration in the tumor, and could be controlled. In this case not only did the torn substance of the tumor bleed, but every detached adhesion poured out blood in abundance.

In reply to Dr. Baer's questions, he would say

that ammonium chloride in some cases of hard uterine tumors is remarkably efficacious in reducing the size of the growths; he has repeatedly seen them entirely removed by the remedy. He had never known ergot to increase the loss of blood during the menstrual period when used for the cure of intra-mural tumors: ergot has a decided effect upon the nutrition of these growths, but he would not expect it to act upon pediculated growths unless inside the cavity of the uterus.

Dr. Henry Beates had been called in consultation to see a case of metrorrhagia. Ten years previously the patient had suffered from miscarriage at the fourth month. Subsequently each menstrual period became more and more profuse and prolonged, until, at the time Dr. B. first saw her, the loss of blood was constant and the patient was pallid and reduced almost to a skeleton, her weight being but ninety pounds. The curette had been previously applied to the endometrium, with the effect of increasing the discharge. Dr. Beates introduced a sound, which passed to the left to a depth of five and a quarter inches; he introduced a laminaria tent of the largest size and next day, by digital examination, discovered a sessile tumor; further dilatation enabled him to remove the tumor by evulsion. It was necessary to divide it to deliver it through the *os uteri*. It was composed of fibrous and muscular tissue, and contained numerous dilated blood vessels which had been the source of the hemorrhage, before operation. Three years afterward the patient's weight had increased to one hundred and fifty pounds.

Dr. B. F. Baer read a report of a case of labor with twins.

Dr. Harris had had under his care a woman in labor with twins. The first one delivered was a female weighing eight pounds; it presented by the breech. After it came away the *os uteri* and soft parts contracted, and an examination made by one who did not know of the delivery of the first child would not have discovered evidence of the fact but for the presence of the cord. The bag of waters presented, and the *os uteri* was again dilated. Three and a half hours after the birth of the first child, the second, a male, was delivered by assistance of the forceps; its weight was nine pounds.

Dr. Horace Williams related his experience in a case of twins. The first child descended in the fourth position, and no rotation occurred, as it was held so by the second child; the pelvis was roomy, but laceration of the perineum resulted.

Dr. R. G. Curtin had this morning delivered a woman of twins; after the uterus was emptied and well contracted a strongly-marked sulcus could be felt in the fundus.

Dr. Drysdale has under his care a woman whose uterus is divided by a complete septum.

Dr. W. S. Stewart inquired if any previous examination indicated a want of symmetry—or if it resembled an extra-uterine pregnancy.

Dr. Baer had not seen the patient until after delivery of the child, and did not ask about the point mentioned by Dr. Stewart. Dr. Goodell has reported a case of supposed extra-uterine gestation in which labor came on naturally. This type of uterus may seem to be very rare, because it is so difficult to recognize. The presence of the septum would never have been suspected in this case had not been found in the attempt to remove the imprisoned placenta.

Dr. Harris said that Dr. Goodell was uncertain of the character of the pregnancy, although every diagnostic test but one indicated that it was extra-uterine. This exceptional condition was the sensation of muscular contraction in the presumed cyst-wall when the hand was applied to the abdomen. Not being able to reconcile this action

with the development of a tubal pregnancy, he determined to trust the case to nature, and sent the woman to the Preston Retreat, where she was delivered naturally in a few days. The uterus was double and was twisted on its axis, and the empty cornu was posterior, admitting the sound in the median line as into an empty organ.

EDITORIAL DEPARTMENT.

PERISCOPE.

Strychnine and Nux Vomica in Infantile Therapeutics.

We take the following rules for the use of strychnine in the disorders of the digestive organs of children from the lectures delivered by Simon in the hospital *Enfants Malades*, in Paris.

There is a form of dyspepsia that you will find in young girls, with faces full of expression, at the approach of puberty when from eight to fourteen years of age. They come complaining of gastralgia, of different forms of dyspepsia; they are generally constipated. After eating the epigastric region becomes swollen, tense and painful; their intelligence is above that of children of their age, but they are capricious, irritable, whimsical; already untruthful, they use far-fetched expressions, affected, and very different from what ought to come directly from the minds of children. These are the links of the chain that unites the neuropathic affections of children to confirmed hysteria. This is one of the favorite formulas of Mr. Simon, for that condition:

R. Tr. of cascarrilla	} aā 5 grammes.
Tr. of cannella	
Tr. of gentian	
Tr. of colombo	} 1 to 2 grammes.
Tr. of rhubarb	
Tr. of nux vomica	

This constitutes a very good aperient, of which ten drops should be given in some wine before meals. If constipation predominates, increase the proportion of rhubarb and tincture of belladonna:

R. Tr. of rhubarb, 10 grammes.
Tr. of belladonna, 3 grammes.
Nux vomica, 1 gramme.

To be given in the same dose and manner as the preceding.

For those who will take powders, he prefers to give this prescription in that form:

R. Powder of crab's eyes, 0.20 centig.
Magnesia calcined, 0.15.
Rhubarb, 0.10.
Nux vomica, 0.05.
Pepsine, 0.05.

If there be intestinal indigestion also, and meteorism becomes very pronounced, he orders the belly to be rubbed with the following liniment:

Tr. of nux vomica,	3 gram.
Tr. of belladonna,	5 "
Camphorated oil of chamomile,	15 "

or with a pomade of the neutral sulphate of strychnia 1 part to 60 of ointment. You will be astonished to see how notably the meteorism will be diminished. The same ointment can be used for prolapsus of the rectum, and also for relaxation of the anal sphincter, so common in old people and children.

In paralysis of every kind nux vomica is much used, either to hasten the return of motion from peripheral or toxic paralysis, or to prevent the degeneration that takes place in muscles condemned to repose, or when the lesion is in their tropic centres.

In diphtheritic paralysis he gives two to five drops of tincture of nux vomica before each meal, insisting at the same time on tonic medication: cod-liver oil, or cinchona wine.

In the grave and extended cases of diphtheritic paralysis it is well to insist strongly on the use of strychnia; from five to ten drops of the tincture of nux vomica must be given at each dose, or from two to eight drops of the following solution, of which the effects must be carefully watched:

R. Sulphate of strychnia, 1 milligr.
Eau, 1 gr.

Infantile paralysis is divided into two stages, the first or febrile, which lasts from six to eight days; at the end of that time, when the child is raised from its bed, the paralysis is first perceived. This is the beginning of the second stage, and it is only during this one that he uses nux vomica in the form of tincture. From five to ten drops during each meal will have the effect of awaking the muscular functions, and of combating the atony of the digestive organs.

In other affections of the nervous system, such as the weakness of the convalescents, the paresis that is brought on by long-continued surgical dressings, and that which follows rheumatism, he employs nux vomica, alternating its use with that of arsenic. He has obtained good results from the arseniate of strychnia.

For chorea he does not use strychnia, because it is a rheumatic affection, and says that it should be treated as such; it cannot be cured, but may be rendered less severe. He knows nothing that will shorten it—its duration being about three months.

In incontinence of urine, when belladonna and

the cold shower-bath have failed in nocturnal incontinence, you may have some hope in strychnia. The diversity of results obtained elsewhere is easily explained by the immediate and predisposing causes of that infirmity. Belladonna is nevertheless preferable to nux vomica, which on the contrary excels when the incontinence is diurnal as well as nocturnal. In those cases of epilepsy that were not ameliorated by the bromides, either simple or compound, Mr. Simon found it well to order strychnia, alternating, about every five days, with atropia. He had two cases at that time that were notably benefited by this treatment, so entirely opposed to the bromides. It is an enigma, he confessed, that was inexplicable. The appearances of cerebral congestion were the same as those in other patients who received the greatest benefit from the bromides.

In concluding he said that strychnia was decidedly contraindicated in marked irritability, in cerebral irritation, in all acute disorders of the nervous centres; but, administered as he has carefully pointed out, it would always give the best results as a bitter, as a tonic, as an excitant of the sensibility, and of the reflex actions.

From the Progrès Medical, Oct. 28.

Treatment of Sexual Neurasthenia.

Dr. George M. Beard, of New York, in his article on the above disease, in the *Medical Record* of December 2, 1882, lays down very explicit rules. We have the division into general, local, and operative treatment: there is no doubt in these cases one plan of treatment is always followed by failure, and that it is only in combining the three divisions together we meet with any success.

The general rules that are to guide us in our constitutional treatment are as follows:

First. Not to place dependence on any one medicine, or any mode of treatment. There is no specific for sexual neurasthenia. The cases are to be treated as cases rather than as diseases. In no form of disease, probably, are idiosyncrasies against drugs and therapeutical procedures more common or more severe than in this disease; they overthrow all our ideas of medicine, and greatly disturb our prognosis; bromides instead of producing sleep may keep awake, tonics depress, etc.

Second. Frequent change of treatment is needed.

Third. Occasional suspension of all treatment.

Fourth. The recognition of the fact that hygiene and medicine are identical, and that those portions of medicine which have been classed under hygiene are more difficult to manage than medical or surgical procedures, partly on account of their inherent complexity, and partly because they are more exclusively in the patient's own hands.

Under what is called hygiene, Dr. B. places diet, work, rest, travel, marriage, change of climate; of these only work, rest and marriage receive any attention—preference is given to work. In many of these cases the patients, if at rest or idle, allow their minds to constantly rest upon their symptoms. "Such persons are not so much diverted as injured by travel; they stand as watchdogs over their symptoms, never allowing them to get out of sight; counting, or trying to count, the healthward progress from day to day, like sailors throwing the log, they are inevitably

disappointed, and return home oftentimes broken and helpless."

In regard to marriage, Dr. B. seems to be somewhat in doubt of its efficacy. Marriage, in my experience, has always proven detrimental. Marriage should not, under any circumstances, be allowed.

MEDICAL TREATMENT.

The medical treatment is divided as follows: Local sedatives, general sedatives, general tonics, mental therapeutics. Under local sedatives are placed epigea repens, triticum repens, stigmata of maize, rhus, aromat. eucalyptus, digitalis and digitalin, alkalies, cantharides in very minute doses, belladonna, atropia, ergot and ergotine, lupatine, camphor, bromide of camphor, gelsemin, cimicifuga—most certainly a large enough list to choose from. It of itself shows the complexity of the disease and the range of medicines which, in some cases, the unfortunate patient has to go through.

In the general sedatives, the bromides head the list; but there are two classes of patients for whom it is not well to prescribe bromides—those kept awake instead of being put to sleep by them, and those who have already taken the bromides too long.

General tonics embrace iron, quinia, phosphoric acid, strychnine, arsenic, etc.

Electricity receives a favorable notice.

Of counter irritation, such as blistering, etc., Dr. B. says, "If severe, it annoys; if mild, does little good."

The surgical treatment consists in relieving phimosis at once by the knife.

Cholecystotomy.

A very valuable paper on this subject was read in the section of surgery at the last meeting of the *British Medical Association (British Medical Journal)* by Mr. Lawson Tait. He said:

On December 20th, 1881, Dr. Lycett, of Wolverhampton, brought to me a lady, aged twenty-eight, suffering from severe paroxysmal pain in the right side, associated with a tumor, which appeared and disappeared. It was found to be movable, situated on the right hypochondrium, and was, in my opinion, distinctly cystic. In spite of the fact that it had been pronounced to be a "floating kidney" by several distinguished authorities, I gave the opinion that it was a gall-bladder, distended by an impacted gall-stone, and I advised the operation of cholecystotomy. Dr. Lycett has favored me with the following history of the case:

At the time of puberty, she began to suffer from pain in the hepatic region, varying in degree and duration, but generally sudden in its onset, apt to be induced by exercise of any kind; and in this way it prevented her from engaging in dancing, and other pastimes. She first came under Dr. Lycett's care in March, 1878, at which time he came to the conclusion that she was suffering from stone in the gall-bladder. One remarkable feature of the case has always been a perfect freedom from jaundice. She had her second child in 1880; and, after that, Dr. Lycett saw reason to alter his view of her case by the discovery of a freely movable tumor in the upper and right part of the abdomen. It seemed solid, and was shaped like a kidney. It

was tender on pressure, and, when the hips were raised above the shoulders, it could be made to disappear. The patient stated that sometimes it could be felt below the umbilicus; but Dr. Lycett was never able to satisfy himself of this. He came to the conclusion that it was the right kidney floating; and Dr. George Johnson expressed a belief that, in addition to this, there must be a calculus in its pelvis to account for the paroxysmal pain. No abnormal condition of the urine was ever found.

After the birth of her third child, she became much worse. Her sufferings were often intense, so that she suffered from serious symptoms of collapse, and she became very thin and anæmic. "Under such circumstances," writes Dr. Lycett, "I advised her to seek your advice, with the object of submitting to abdominal section, in the hope of that possibly affording relief. To this measure, however, she took some six months to make up her mind, but finally consented when she had become a chronic invalid and almost bed-ridden."

I saw her with Dr. Lycett last December, and was fortunate in discovering the tumor at once. It seemed to me to be cystic, to be attached above, and therefore I pronounced it to be the gall-bladder distended, on account of the occlusion of the duct by a calculus. I put the floating kidney theory altogether on one side, because I have never seen such a thing, either in life or in a museum, nor have I met any one who has. In fact, I have no belief in its existence as a pathological incident.

I proposed to open the abdomen and remove the calculus, but, as Dr. Lycett says, she took six months to make up her mind to the operation. She came back to me early in June, very much reduced in health, and on the 15th I opened the abdomen by a vertical incision over the tumor. I came at once upon it, and found it to be the gall-bladder distended. I emptied it by the aspirator, removing about a pint of thick glairy mucus. I then laid it open, and removed about eighty gall-stones of small size, the largest weighing fifteen grains. They were removed chiefly by the use of a *curette*.

I then stitched the aperture in the gall-bladder to the wound in the abdominal wall, carefully closing the peritoneum, and leaving a drainage-tube in the gall-bladder. The patient's recovery was uninterrupted; the highest temperature recorded was 100.4°; and the highest pulse record 84. The stitches were removed on the eighth day, the drainage-tube on the twentieth day, and in ten days more only a small sinus was left, from which some mucus still continues to be discharged. The patient has gained flesh since the operation, and has been entirely free from pain.

Neither at the operation nor in the after treatment were any of the "antiseptic" methods of Professor Lister employed, as I have entirely discarded all these for about two years, with great advantage to my patients.

The fistula in the gall-bladder continued to discharge clear mucus till on August 5th, when "something seemed to give way," as she said, and bile flowed freely. This is very satisfactory, as it shows that the occlusion of the duct has been overcome, and the complete functions of the organ may be re-established by the closure of the

fistula. This I shall take means of securing shortly.

A FOURTH CASE OF CHOLECYSTOTOMY.

A. B., aged 37, was placed under my care some weeks ago by my colleague Dr. Hickinbotham. A tumor in the position of the gall-bladder could be occasionally discovered, and she suffered intermittently from severe attacks of cholic. It was clearly a case of distended gall-bladder. On October 13th, I performed an operation precisely similar to that narrated above, and removed sixteen gall-stones, varying from seven grains to thirty-five in weight. I removed the drainage-tube on the third day. The stitches are now (October 24th) all removed, and the wound is almost healed.

From the recent epidemic of typhoid fever in Paris we may derive some important information. Of its magnitude some notion may be formed from the fact that on the 22d of October there were in the hospitals 2,175 cases of typhoid fever. From that time the epidemic progressed in the following manner: On the 23d, 50 cases entered, 72 went out, 9 died; remaining on the evening of the 23d, 2,141 cases. On the 24th there were 77 entered, 72 went out, 9 died; on the evening of the 24th 2,137 cases remained. On the 25th, 25 entered, 54 went out, 10 died; there remained in the evening 2,131 cases. On the 24th of October there were 25 internments of those who died from typhoid fever, and on the 25th there were 11 from the same. From the 15th to the 25th the daily entries varied between 25 and 77; whereas, from the 9th to the 14th, they varied between 86 and 180; the epidemic seemed then to be declining.

During the epidemic, of course, ample opportunity was given for a trial of the various treatments.

Carbolic acid has been unfavorably spoken of at a discussion by the "*Société Médicale des Hôpitaux*," for though it lowers the temperature, it does not, in any way, modify the march of the disease; and those who some time since vaunted it so highly have ceased to use it on account of the great danger attending its exhibition.

M. Siredey no longer uses rectal injections of carbolic acid except to modify the offensiveness of the stools, and moreover, immediately after having given the injection, he gives a large one of water to secure an evacuation so as to prevent absorption.

M. Vulpian has tried iodoform, salicylate of bismuth, boric acid, carbolate of soda, and salicylic acid. Of iodoform and also of boric acid he used as much as 180 grains a day without any effect; 135 grains of carbolate of soda gave the same result: 180 grains daily of salicylate of bismuth lowered the temperature, disinfected the stools, and gave general amelioration, but there was dyspnoea, nasal and intestinal hemorrhages. He then gave salicylic acid powder in wafers, using 90 to 105 grains in 24 hours, the doses given at intervals of two hours, and each dose followed by the ingestion of a little soup or wine. In general, the remedy was well supported. The only accident that seemed attributable to the salicylic acid was a little delirium. It caused neither dyspnoea nor hemorrhage. There was lowering of the temperature as from phenic acid, but it lasted longer. The general condition was favorably modified.

The duration of the fever was not influenced. M. Vulpian concluded that without being a curative agent, it had a sufficiently moderating influence to merit it a place among the best modes of treatment. He proposes it as a prophylactic; a healthy man will bear as much as 30 grains a day without any inconvenience.

Bouchard called attention to turpentine, a powerful antiseptic agent, and unfortunately a little neglected in these researches.

Ergot seems to have given most satisfaction. Taken in doses of 15 grains a day, the pulse fell, the temperature was lowered, delirium was stopped, and also other grave symptoms.

M. Duboné gives 30 to 45 grains a day for an adult, and from $\frac{1}{2}$ to 15 grains for a child, according to its age.

Dr. Guichard thinks these doses large, and commences by doses of 15 grains a day for adults. To children he gives from $\frac{1}{3}$ to $\frac{1}{4}$ of a grain, according to age.

Pneumo-Uria.

Prof. E. L. Keyes, of New York, contributes an article to the *Medical News* of December 16, 1882, entitled *Pneumo-Uria*, which disease is characterized by the formation of a gas in the bladder, resembling air, colorless, sweet and pure, not ammoniacal, not sulphuretted hydrogen, and not introduced from without. Two cases are cited which indicate the existence of this peculiar malady.

In the first case the remarks are quoted from memory. In brief, a gentleman aged sixty-seven, after some years of treatment for prostatic trouble, died from renal disease produced by this obstruction. During life it was remembered that he had passed gas per penem. At the autopsy, the bladder was found distended with gas, and yet no fecal matter nor vesico-intestinal fistula was found in the bladder. The urine was not putrid, nor had it contained foreign matter. Unfortunately the case was not more carefully recorded, and Prof. Keyes remarks he presents it "for what it is worth."

In the second case, a gentleman applied for treatment on account of frequent micturition and the passage of gas by the urethra. The urine was not putrid, the gas was odorless, and contained no sulphuretted hydrogen, except on one occasion, when the urine became ammoniacal and decomposed, and probably was free from carbonic acid, as the urine did not contain an excess of carbonates. Indeed, Prof. Welch pronounced it to be simple air. The crucial test of an autopsy was absent, but the symptoms excluded intestinal fistula, the track of an abscess or a cancerous erosion as the means of entrance into the bladder of this gas. Two similar cases are reported by Widell and Raciborski. Of course these cases do not prove the existence of pneumo-uria; but they should stimulate investigation, and if possible be the starting point of establishing this strange malady upon a sound basis.

The Study of the Face as an Index of the Brain.

Dr. Francis Warner read a paper on the above before the Section of Medicine of the British Medical Association, which possesses much interest.

The face is a region of the body well worthy of

clinical study. We may observe its form, color, and mobility; and the effects of movement in causing expression. The movement is the outcome of the action of the brain.

The tissues forming the structure which we call the face are mainly the skin, with its vessels and vaso-motor system; the subcutaneous fat; the facial muscles, supplied by the facial nerve; and some of the masticatory muscles, supplied by the fifth nerve.

Most of the variations of facial expression are produced by the facial muscles, which are acted upon by the changes in the brain; and these are the special indications of the cerebral condition to which attention will here be called. The muscles of mastication are less expressive of the condition of the brain than are the facial muscles; but they may become the subject of spasm, atrophy (see Case, *Lancet*, January 7th, 1882), or may produce teeth-grinding, as the result of conditions of the brain.

In almost all cases, the best indications of the conditions of the central nerve mechanism are its effects as seen in the spontaneous action of the muscles; and it is by the result that we usually judge of the central condition. Such effects are conveniently spoken of as nerve-muscular signs. Nerve-muscular signs are the best indices of the brain; the change in the brain affects the muscles; these control the position of the visible parts; and, from the facial changes resulting, we gather our information.

We are here studying the results of cerebral action upon muscles, according to well understood principles of physiology; while physiognomy deals mainly with the shape of the brain-case, and the passive condition of the face.

The principal movements of the facial muscles are these:

1. Dilatation and contraction of the facial foramina; probably this corresponds in significance to flexion and extension.

2. Elevation and depression of parts. Such conditions are well seen by comparing the two sides of the face in a case of Bell's paralysis.

3. Retraction and drawing forward of parts, as in grinning and screwing up the mouth.

To examine a face, hold a piece of paper in front of it, with one edge vertical; either half of the face can then be covered in turn. Again the face may be divided into three zones, by holding the paper with one margin horizontal, leaving the forehead above the eyebrows uncovered; or, the face below the lower margin of the orbits may alone be exposed, showing the mouth, most of the cheeks, and the *alæ nasi*; or, again, the middle zone, including the eyes with the upper and lower eyelids, may be viewed alone.

After looking for symmetry in a face, the nerve-muscular condition of the individual parts may be compared. A different condition of the different zones has, possibly, about the same kind of significance as an unequal condition of flexion and extension of the different fingers. A condition of different activity in the three zones of the face is a departure from physiological calmness (*e. g.*, a smile, or snarl); it may be normal or abnormal. An unequal condition of the different zones is very common in "nervous people."

In the upper zone, we have the occipito-frontalis and the corrugator supercillii. Here we see the

outcome of brain-action in those conditions termed grief, surprise, etc., producing muscular action and corrugating the forehead. The occipito frontales are often seen overacting in imbeciles, and in cases of chorea; sometimes, also, they overact as a mere "chronic nervous habit." Symmetry in this zone is usually maintained. In the middle zone asymmetry is less uncommon, but is seen in winking and in ptosis. The important muscles here are the orbiculares oculorum. With megrim, and in conditions of depression, a marked change is often seen in the midfacial zone, due to a fullness about the eyes, especially about the under eyelids; the orbiculares have lost their tone; the skin hangs too loosely; the skin of the lower eyelid, instead of forming a convex surface, passes as a plane from the ciliary margin to the lower margin of the the orbit. If the patient be made to laugh, the orbiculares are energized for the moment, and the look of depression is lost.

Passing on to the consideration of the lower facial zone, we see here the most marked effect of facial spasm or palsy from brain-disease—*e. g.*, in hemiplegia and lesion of the crus cerebri. Thus the weakness of the face is well demonstrated by making the patient show his teeth or smile. Now, the muscles of this region are those most commonly seen in spontaneous action in imbeciles; it is these muscles that work awkwardly in nervous one-sided grinning, and in this region we most commonly see asymmetry of the features, due to nerve-muscular conditions. It is interesting to note that this region of the face is the most affected by brain-disease (paralysis), and in "nervousness" (irregularity of the mobile features). Again, it is the levator labii superioris in the lower zone which produces one-sided snarling, one of the lowest expressions produced by the human face. In complete development and perfect health the features are usually regular in passive form and in symmetry of movement. In most expressions, the symmetry of bilateral movement is complete; from this we infer that the nerve-mechanisms for each side of the face are intimately connected.

In observing how easily facial asymmetry is brought about, we see evidence that the union of the facial centres is easily dissolved and not very strong, the asymmetry being especially seen in the lower zone; thus asymmetry is produced by nervousness (see one-sided grinning), by the desire to attack (see *Darwin on the Expression of the Emotions*, page 250) (snarling), or by such defective nutrition or development as produces unequal features when in motion. The higher, more intelligent expressions, are symmetrical. Union of the facial centres is less perfect than the union between the motor centres of the eyes, for the cerebral condition producing "emotion" cannot cause dissociated movement of the eyes. We find here an illustration that symmetry of action, as well as symmetry of structure, is part of the law of beauty.

It may be remarked as a peculiarity of the facial muscles in man, that they are usually free or disengaged, not mainly occupied in doing a definite work, but their movements are mainly the spontaneous outcome of brain-action. The facial muscles are usually very mobile, and often illustrate the struggle of nerve-muscular actions; this may be seen in the conflict of the muscles about

the mouth in the endeavor not to cry. The study of nerve-muscular signs in the limbs shows the importance of observing whether "the movement of small parts"—*e. g.*, the fingers—be thoroughly good; this kind of observation in the facial region is, I think, represented by "the finer movements of expression." These are totally absent in some cases of paralysis agitans, although the larger movements of the face can be voluntarily performed. When fatigued, the brain does not act well in producing the small, fine movements of either hand or face. We sometimes see a nervous play of the features; this, I imagine, depends upon slight irregularity of the muscles producing slight movements. In convulsion, both clonic and tonic, and in tetanus, the larger muscles usually produce the most marked effect.

In observing different types of face, we become at once struck with the fact that some faces express intellectuality, others vulgarity; some faces are very mobile and very expressive, others are passive and immobile.

The peculiarity of vulgar faces may be roughly divided into two elements: 1. Physiognomy or the shape of the brain-case and face, together with the character of the facial tissues, and the structure of the features and parts of the face. Here, probably, we have an example of the coincident defective or coarse development of the face and the brain. This illustrates the relation of morphology and function, the structure of the face, and the coincident structure of the brain which moves the face. Elements contributing to this character of face are a large under jaw, a thick immobile condition of the facial skin, thick lips, etc. It will be seen that these are mainly conditions in the development increasing the protective character of the skin of the face; the thick immobile tissue is better able to resist the action of external agencies, but it is also less mobile under the action of nerve-muscular changes. The large lower jaw may be very useful for mastication or defence, but it does not serve to increase the play of nerve-muscular actions.

2. The second typical characteristic is the nerve-muscular condition of the face. Such signs are more directly indicative of intellectuality of the brain; hence we should study a face as the index of the brain, when it is seen in action as well as when at rest. The mobility in the different zones and the relative condition of these areas give indications of the condition of the mental nerve-mechanism. These considerations afford some evidence that facial expression results from nerve-muscular action, the outcome of the motor action of that part of the nerve-mechanism which produces mental states.

A Meteorological Antiseptic.

An exchange states that a remarkable instance of the beneficial influence of tropical storms has just occurred in the Philippine Islands. The population of Manila was being decimated by cholera, when, at the end of October, a tremendous hurricane swept over the island, almost entirely destroying the town. On the following day not a single case of cholera occurred, and not one has been reported in the island since.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—The Annual Report of the National Board of Health for 1882 is a document that ought to be carefully read by every member of Congress. It would serve to enlighten that honorable body as to the great economic value of the Board, and to prove that the charges made against it are and were wholly unfounded. Its appropriations were economically and judiciously expended, and it is to be hoped, will be renewed and increased in the future.

—Some valuable suggestions on the treatment of phthisis and the importance of laryngeal symptoms in its diagnosis are presented in a reprint by Dr. M. F. Coomes, of Louisville, Ky. One of the points to which he draws especial attention is his conviction that it is possible to make a positive diagnosis of the existence of pulmonary phthisis by means of the laryngoscope, before such diagnosis is justified by other physical signs or symptoms.

—The change of the *New York Medical Journal* from a monthly to a weekly, adds another to the medical periodicals of frequent issue in our neighboring city.

—We learn with pleasure that the fifteenth edition of the United States Dispensary will be ready this month. The editors are Dr. H. C. Wood, Professor of Materia Medica and Therapeutics in the University of Pennsylvania, Joseph P. Remington, Professor of Pharmacy, and Samuel P. Sadtler, Professor of Chemistry in the College of Pharmacy of Philadelphia. The revision has occupied about three years, and has been in all respects most thorough and complete, embracing the most recent discoveries in Materia Medica, Pharmacy, Chemistry, and Therapeutics.

—Dr. Rollin T. Gregg, of Buffalo, New York, continues his investigations into the nature of tubercle. He denies that they are caused by bacteria, and claims that chyle corpuscles, red blood corpuscles, and tubercular corpuscles, are the same, only under different conditions. His reprints may be had of the author.

—Dr. A. L. Chapman, of Kansas City, Missouri, begins with the year a monthly journal on sanitary science entitled, "*The New Medical Era and Sanitarian*," subscription price \$1.50 per year. It will contain foreign and domestic news in this branch, and will, we doubt not, merit a large patronage, which we hope it will also not fail to receive.

BOOK NOTICES.

Annual Report of the Supervisory Surgeon General of the Marine Hospital service of the United States. Washington, pp. 304.

No one can look over this volume without being gratified that our government provides for the continuance of this bureau. It is managed with efficiency and economy, and there are few appropriations which so well repay their expenditure as that for the support of this service.

The document contains the official report of the secretary, a mass of statistical matter—medical and surgical, the detailed description of a number of selected cases from hospital practice, records of autopsies, and, in the appendix, a very excellent, and we may add touching article by Surgeon Walter Wyman on the hygiene of steamboats on the Ohio river. The sufferings of the poor "roustabouts" are described with a sad fidelity, and we cannot but wonder both that men are found willing to bear such hardships, and that there are others ready to inflict them.

There is a variety of other official information in the volume which renders it of much interest to the profession and the philanthropist.

A Treatise on Fractures. By Lewis A. Stimson, B. A., M. D., etc., with 360 Illustrations. Philadelphia, H. C. Lea's Son & Co. 1 vol. 8 vo., pp. 598, Leather.

Dr. Stimson is already known to the public by some surgical writings of excellent character, and the present volume will add to his reputation. It is very carefully composed, and the many difficult and obscure points which present themselves in treatment of fractures receive a clear and usually convincing discussion.

Such a volume will be welcome to very many readers, as there is no rock on which a physician's reputation is so often shattered as on his treatment of fractured bones. Probably ninety per cent. of the cases of mal-practice arise here, and the practitioner cannot fortify himself too strongly with good authority for his procedure.

Dr. Stimson's earlier chapters are on the varieties and etiology of fractures, their symptoms, diagnosis, methods of repair, complications, remote consequences, general treatment, general prognosis, vicious union, etc. He then proceeds to discuss the fractures of each of the bones, giving both general rules and illustrations from special and anomalous cases. In this he draws from an extensive personal observation, as well from a wide reading.

We believe his book will take a high position among the monographs on this branch of surgery, and it is the evident result of a careful study of the subject.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

THE NEW YEAR.

Standing at the threshold of a new year, it is pleasant and not unprofitable to forecast its probable activities in the departments of thought which most concern us.

In medicine it appears that the practical side, the clinical features of the art, will in 1883 receive the most attentive consideration. There have been so many breakdowns lately of fine-spun theories as to the causes of disease, that the medical mind is wearied of them. Too often they have proved but attractive cobwebs, unable to hold even a grain of fact.

Pathology, too, has not returned the expected harvest. The magnificent construction of the cellular theory has cracked ominously, and threatens to tumble about its creator's ears. The zymotic hypothesis is scarcely in a more stable condition, and the thousands of pages printed in support of it seem destined to the lumber-room.

A sense of weariness with these almost fruitless doctrines is creeping upon the mind of the profession.

What will be the result?

We doubt not it will be healthful and good.

We shall turn back once more to the advice of Sydenham, and make our place of study not the dissecting-room or the laboratory so much as the bedside. Disease and not the products of disease, physiology rather than pathology, therapeutics rather than experiments on drugs, will regain the attention which, in a measure, has been diverted from them.

Hygiene and sanitation will rise more and more in importance. The prevention of disease, the lengthening of life, the lessening of pain, heightening of vitality—these are the problems of the hygienist, and when he shall have solved them to the utmost possible extent, he will have accomplished more good than all the theologians who have raved and written since the world began. The task is great, the prize the greatest.

“Kühn ist das Mühen,
Herrlich das Lohn.”

Such we believe to be the probable future of medicine in this and the coming years. Though

it may lag or falter by the way, sooner or later it will adopt these as its true paths to the highest possibilities.

THE VALUE OF PRACTICAL MEDICAL JOURNALISM.

There are two classes of physicians, and, to a certain extent, two classes of medical journals.

There is the scientific physician, whose time is devoted to the study, investigation and elucidation of the, as yet, mysterious and unknown phenomena of disease; who in the privacy of his laboratory, his anatomical room, or his exclusively hospital practice, is constantly seeking to throw light into the dark and narrow paths of progression towards the goal of an *exact* science of medicine.

On the other hand, we have the practical physician, who is constantly going about from one scene of pain and sickness to another, whose sole thought is to relieve distress, and to do so as rapidly as possible.

To him it makes no difference whether typhoid fever is caused by a bacillus or not; the ultimate etiological factors of disease have no interest for him; his is a practical mind, and if you teach him, in the first place how to avoid disease, and in the second place how to assist nature to cure when disease has been contracted, you furnish him all that he requires.

There are, of course, many men who hold positions between these two extremes; but the large majority belong to one or the other, and in the ranks of the practical army are to be found the great mass of our profession.

The scientific class originate certain ideas and experiment with them, until it seems they have demonstrated certain truths, when these results are given to the working class, to see whether they will bear the severe test of extended practical application.

Medical journalism, broadly speaking, is the means of intercommunication between these two classes, as well as between the individual members of each.

The scientific medical journal reflects the

thoughts, observations, and experiments of the scientific physician.

The practical medical journal reports for its readers all that may be of practical use to them in the prevention, recognition, and cure of disease.

A practical medical journal is prepared somewhat as follows:

Reports of interesting cases occurring in private practice, wherein some unusual phenomena have presented themselves, or where some drug hitherto unused in this particular diseased condition has given good results, or some highly vaunted remedy has failed, are found in its original departments—thus making itself a depot in which is accumulated the practical experience of many men with many drugs, furnishing a perfect mine of knowledge for constant reference.

Then come society and hospital reports, giving the views and experience of the very leaders of the profession in the great medical centres.

The new books receive a notice, that the busy physicians may learn what to buy and read.

Then comes really the most valuable portion of the practical medical journal. From all sources, from thousands of journals and volumes, the editor and his numerous assistants cull carefully all that may be new and practical, and present them to their readers.

In a scientific medical journal he may read an article four pages long, in which he recognizes something valuable to the busy doctor; he distills it, as it were, and in fifteen or twenty lines (or in some instances perhaps a column) he furnishes all that really has a practical bearing on the practice of medicine. The reader has but little conception of the immensity of the labor involved in this distillation and condensation.

In a word, the practical journal is, to the practical physician, what the Bible is to the practical Christian; only it is more essential, since a man may be a Christian who does not own a Bible, but it is an absolute impossibility for a man to be a busy and successful practitioner, unless he constantly and regularly reads a *practical* medical journal, which will mirror to him the medical progress of the world.

NOTES AND COMMENTS.

Obstruction of the Bowels.

Though we seldom have unusual cases of obstruction of the bowels reported by American physicians (why, we cannot comprehend, unless it is that they fail to report their unusual cases), yet such cases are frequently found in foreign journals. One of the most instructive that we have lately encountered is reported in the *London Practitioner*, by Dr. J. Dickson Hunter, of Peru. A healthy man, aged 50, complained of severe pain in the abdomen; his bowels had not been moved the day previous. Pulse and respiration frequent, tongue red and dry, abdomen enormously distended, and temperature above normal. There was considerable suppression of urine, and vomiting of a slightly discolored water; occasional hiccough. A rectal tube and a No. 10 catheter could only be passed some two or three inches. An aspirator trocar was plunged into a particularly prominent part some three inches below the ribs on the left nipple line. Immediately, flatus could be heard and smelt escaping. Lighted matches were, at intervals, held before the trocar, and were quickly extinguished. When, at last, one burnt steadily, the instrument was withdrawn and oiled lint applied. The distention was somewhat lessened, but the next day was as bad as ever. He was chloroformed, and the hand introduced into the rectum. When it had passed for eight inches, it was found to be comparatively free, in a vaulted cavity without any apparent exit. Upon careful examination, a slight projection was felt, something like a soft, but not prominent os uteri, with a central depression. By inserting one finger at a time, the hand was gradually passed through this depression, into a large, roomy cavity, in contact with a soft pulsatious substance. From the tip of the middle finger to the point where the arm was grasped by the anus, measured sixteen inches. A long tube was now passed along the arm and hand, which gave exit to a dark green semi-fluid, and flatus. The hand was withdrawn, and as the fluid was escaping slowly, warm water was injected, which caused a copious discharge. He made a rapid recovery.

How to Make a Poultice.

The editor of the *London Practitioner* offers numerous apologies for calling the attention of his readers to a matter seemingly so trivial; but his wise remarks show that his article needs no excuse, since we can easily recognize that it is just upon these important little details that the average practitioner is but imperfectly informed.

He notes the fact that heat and cold will each often have the same effect on an inflamed part; the cold by causing the afferent arteries to contract and diminishing the amount of blood sent to the inflamed part; the heat by dilating the capillaries and affording a ready side outlet into the veins; in both cases, relieving the impact in the inflamed part. But the common practice of placing the linseed, or whatever may be used, directly on the surface, will not exert as much influence as though we allow the heat to penetrate directly to the diseased organ or part. He therefore recommends making a flannel bag, say 12x8, closed at three edges and open at the fourth. The linseed, bowl and spoon used in making the poultice should be well warmed in hot water, the poultice should be made with boiling water, and rather soft. The bag should be warmed by holding before the fire, before the poultice is poured into it, and being quickly wrapped in a strip of flannel (previously warmed), should be applied to the part. Thus the poultice may be applied to the skin, boiling hot, without burning. The two layers of flannel, which are at first dry, allow the heat to pass very gradually to the skin; as the moisture of the poultice soaks through them, they become better conductors, and the heat passes more quickly; but the increase is so gradual as not to cause any painful sensations whatever, but only one of soothing and comfort. The poultice also naturally keeps much longer hot, and the necessity for changing it arises much less frequently.

He has seen patients suffering from intense abdominal pain, at once relieved by a poultice made in this way; and so have we. These little points are too often neglected, and we can promise gratifying results to those who will commit these directions to memory and put them into practice.

The Radical Cure of Hernia.

Once more we are presented a new operation for the radical cure of hernia; W. Mitchell Banks, in the *British Medical Journal*, describes an operation by which he "ligates the neck of the sac, with excision of the sac and stitching together the margins of the abdominal opening" (the pillars of the ring).

He presents a table of 21 cases in which the operation was done for relief. In 15 of these cases the patients are now at work, (cured?) This upon a superficial glance appears to be a brilliant result, but 21 cases are a very small number on which to base the claims of a "radical cure" of any disease; and furthermore, few of the so-called successful cases have been kept under observation

sufficiently long to ascertain the permanency of the cure.

When an authority such as Prof. D. Hayes Agnew tells his students year after year that he views with distrust any operation for the radical cure of hernia, and advises no further interference than the application of a *properly*-adjusted truss, the profession in America will at least be on their guard for "radical cures."

Anæsthesia by Rapid Breathing.

If a person is directed to breathe hard and rapidly for some time, a condition of anæsthesia is soon produced, in which there is complete relaxation of the muscular system.

It is not an easy task to get a patient to do this effectually. One has to urge the patient. "Breathe hard, deeper, faster. Still keep on! Do not stop!! Just a little more," etc. The effect will be most marked, the contracted muscles will relax, and a general "limp" appearance will be noticed; this is the moment to seize for the reduction of dislocations, incarcerated or strangulated hernia, etc. This method, as W. A. Berridge points out in the *British Medical Journal* of November 25, 1882, is one to be borne in mind by country practitioners, and in fact at all times when anæsthetics are not procurable.

Therapeutic Effects of Hyoscyamine.

Dr. Thomas Brown presents us a very readable little article in the *British Medical Journal* of November 25, 1882, upon the effects of the hypodermic injection of hyoscyamine in the violently insane and in cases of general paralysis of the insane with unceasing motor activity.

The practical lessons deduced from the paper are:

1. The observations show the uncertainty of the action of hyoscyamine when given by the mouth, and the danger of larger doses.
2. They also show the marked superiority of the hypodermic method, and the confidence with which, in some cases, its efforts could be calculated on, and the dose increased or diminished in accordance with the violence of the patient.
3. In hyoscyamine we have a drug which is often capable of controlling the violence of a furious maniac, and it may be, checking the torrent of rushing ideas on which he is borne along, soothing without putting him to sleep, and, in these respects, differing from morphia or chloral. In noisy and destructive general paralytics, the quiet air of comfort and repose following a moderate dose was such a contrast with the previous condition, as to strongly impress every one with

the feeling that, by the introduction of hyoscyamine, another valuable aid has been secured in the care and treatment of such cases.

4. No curative action can be claimed for the drug; it does nothing more than moderate or check for a time the violence of action, and, perhaps, render less vivid and overwhelming the terrifying whirlwind of delusion of the frantic patient.

The following is the doctor's formula:

R.	Hyoscyamine,	gr. iv.
	Glycerinae,	
	Aquæ distil, <i>āā</i> ,	f. $\overline{3}$ ss.
	Acid carbolici,	$\overline{\text{M}}$ ij.
	Dissolve without heat.	
Dose—	4 to 8 $\overline{\text{M}}$ hypodermically.	

Puerperal Peritonitis with Metastatic Abscesses.

A young woman 17 years of age entered the service of M. Empis at the Hotel Dieu with all the signs of puerperal peritonitis. She was confined 15 days previously, and had presented no sign of fever or other trouble until a day or two previous to entering the hospital, when she commenced to suffer from abdominal pain and fever. When seen in the service she was in a state of extreme prostration; the abdomen tympanitic and painful on pressure. The lochial discharge was fetid, the temperature at 104.°C

Five days later the patient died rather suddenly in syncope. At the autopsy a small quantity of pus was found in the peritoneal cavity. The uterus was very large, and its cavity transformed into a vast purulent surface. Small metastatic abscesses were found in the lungs, spleen, and several in the columnæ carneæ of the heart.

Tuberculous Synovitis of Tendons.

At a recent meeting of the Société de Chirurgie, M. Ferrier read an important communication on tuberculous tendinous synovitis. After M. Debove recognized the presence of tubercle in a case of synovitis at the carpus, M. Lancereaux described the affection, and more recently M. Trelat and Debove have met with cases.

M. Ferrier has observed three new cases, where microscopic examination by himself and M. Malassez demonstrated the presence of tuberculous granulations.

Clinically, most cases resemble the type described by M. Lancereaux, but some cases resemble acute tuberculosis of the joints, and the symptoms are similar to those observed in acute synovitis with effusion.

The diagnosis is difficult. The affection may be essentially local, or may be merely a local manifestation of a general infection of the system.

Mercurial Glycerite.

The absorption by the skin of any medicament incorporated with a fatty substance is very feeble, except for mercurial ointment. According to M. Vigier (*Gaz. Hebdomadaire de Médecine*), any substance incorporated with glycerine (iodide of potash, chlorhydrate of morphine, etc.) is not absorbed. He considers that this property of glycerine is due to its not wetting the skin. Experiments on himself and his élèves have proven that the active substance thus incorporated never produces its constitutional effects. It is for this reason that he recommends glycerine instead of lard in mercurial preparations for scabies, pediculi corporis, etc., as they have an antiparasitic effect without being absorbed. The following glycerite, notwithstanding the caustic nature of its principal ingredient, may be used without danger:

R. Hydrarg. bichlorid., $\frac{3}{4}$ iss.
Glycerine, $\frac{3}{4}$ iij. M.

Aspidospermine (Quebracho).

The powder of the bark of a tree (*aspidosperma quebracho*) found in the Argentine Republic, was first used in Europe by Penzoldt, of Erlangen as a remedy in dyspnoea.

According to M. Burgos, the powder of white quebracho has all the physical and organic properties of powdered quinquina, and is also antiseptic. The decoction is employed as a tonic and febrifuge.

It produces a diminution in the frequency of the pulse and respiration (Berthold, Picot, Berger, Laquer).

If used continuously for a period, it induces cephalalgia, vertigo, dullness of the intellectual functions, and abundant salivation (Laquer, Berger).

This bark contains tannin in abundance, and two alkaloids, aspidospermine and quebrachine; this last is said to have an action similar to that of curare. The sulphate and chlorhydrate of aspidospermine are very soluble, and the solutions are very bitter. The chlorhydrate has been employed by Penzoldt. The following solution for hypodermic injection is indicated in the *Medical Kalender und Rezept-taschenbuch für die Ärzte des deutschen Reiches*, 1883.

R. Aspidospermine gr. xv.
Aque destill. $\frac{3}{4}$ xij.
Ac. sulphuric, q.s.

Twenty minims is a dose, containing nearly one-half grain of the alkaloid.

Aspidospermine and its salts have appeared efficacious in dyspnoea, no matter whence its source (Penzoldt, Picot, Skoda, Krauth).

Surgical Treatment of Caseous Swollen Lymphatic Glands.

Dr. L. V. Lesser, who has for himself achieved a reputation by several simple operative procedures, which have met with universal approbation, and have taken the place of older, more complicated ones, now proposes the following surgical treatment of swollen caseous lymphatic glands, the removal of which, as our readers will know from several articles we published on this subject, is always indicated, as such glands, when breaking down and sending their contents into the circulation, are apt to give rise to tuberculosis (*Cbl. f. Chir.*, 1882, No. 22). Lesser makes a small incision into the skin, and from there he removes subcutaneously with a steel spoon not only the caseous glands which lie immediately under the cut, but also those caseous glands which he finds in the neighborhood. Perfectly aseptic precautions (spray and everything) are conditions *sine qua non* in this operation, after which, if these cautions have been observed, never any fistula followed, but somewhat round, superficial, and very small cicatrices are all that is left of the former glands and as the result of the operation. Skillful manipulation with the spoon will totally exclude any possibility of injuring an important blood vessel. The success of this operation, compared with that of former methods, was, as far as concerns the absence of pus and of unsightly scars and rapidity of healing, so great that we did not wish to withhold a description from our readers.

The Treatment of Diphtheritic Sore Throat.

Every now and then we meet an epidemic of a form of sore throat which, in many particulars, resembles diphtheria. The onset is sudden. The disease is ushered in by chilliness or actual shivering, followed by fever, loss of appetite, headache and pain in the throat, aggravated by swallowing. On examination, the tonsils, the arch of the fauces, and in many cases the uvula, are red and swollen. Occasionally small ulcers are seen. The cervical and submaxillary glands are frequently swollen, and in some cases albumen is found in the urine. The temperature may reach 105, while the pulse is much accelerated. It is distinctly infectious, for wives become affected subsequent to their husbands, and in some families all the members are attacked. Such an epidemic has recently appeared in Edinburgh, and Dr. Allan Jamieson, who makes a report of it in the *Edinburgh Medical Journal* for December, has found the most marked benefit to result from the internal administration of salicylate of soda and the local application of a solution of boro-glyceride in glycerine, frequently during the day.

Non-Antiseptic Dressings.

At a recent meeting of the Soc. de Chirurgie, M. Desprès presented a patient who had undergone amputation at the thigh for white swelling.

No antiseptic precautions whatever were taken. The two flaps were brought together and held in position by long bands of ordinary adhesive plaster; no sutures were used. The entire stump was then covered with lint, spread with ordinary diachylon ointment. The result was excellent, and cicatrization was complete in twenty-eight days, so that M. Desprès was enabled to present the patient to the Society.

From across the channel comes the communication of Dr. Lawson Tait, read before the Medical Society of Worcester (*Progrès Medical*, November 18, and *British Medical Journal*, October 23, 1882).

In one hundred cases of ovariectomy, Dr. Tait lost but three patients, and one of these through accidental suffocation. Among these patients six were encephalic at the time of the operation, and but one aborted, the others arriving safely at full term. Four of the patients had acute peritonitis, but all recovered.

Dr. Tait attributes these remarkably favorable results to improved methods of operating, and to the entire absence of phenic acid or any other antiseptic method of treatment either during or after the operation.

General Paralysis.

Dr. Philip Tenner, in the *Cin. Lancet and Clinic*, defines the disease as an affection of the anterior portion of the cerebrum, of that part which the study of comparative anatomy and anthropology indicates to be the seat of intelligence, and which modern experimental investigations indicate to contain the motor centres. The pathological anatomy consists of changes in the membranes of the brain, usually most marked in the anterior portions, as well as changes in the cortex and subcortical regions, affecting chiefly the anterior cerebral convolutions. Its earlier symptoms consist chiefly of morbid manifestations of intelligence, such as want of judgment, loss of memory, boastfulness, etc., and of failure of the motor functions occurring simultaneously and progressing correlatively with the mental disturbances.

The Cause of Sick Headache.

Apropos of the two articles that have appeared on this subject in our columns, the following communication from Dr. A. Cordes, of Geneva, to the *British Medical Journal*, possesses a special interest. "Being very short-sighted at the age of 15, I went to Dr. X., who prescribed to me No. 8 focus, for reading, writing, etc.; No. 5 to be used only for

seeing at long distance; and to remain without any appliance for the other acts of life. As soon as I was under this treatment, I suffered most painful continuous headache, located in and around the eyes, which made me sick sometimes. Consequently, I made up my mind to wear constantly any spectacles which would suit my sight. I began with No. 8, going on progressively till at the end of the scholastic year I went to 3½, which I wear since that time constantly, even when bathing or swimming in the sea. As soon as I did so, my headache disappeared, and has not returned, unless brought on by some other cause.

I may add that a Genevese and a London oculist have both ascertained the existence of astigmatism in my right eye, for which I wear a cylinder concave glass, wearing No. 3½ on the left.

Adulterations of Oil of Gaultheria.

The *Cin. Lancet* says: The oil of gaultheria now recommended for acute rheumatism is sometimes adulterated with oil of turpentine, birch, and also with alcohol.

Excretion of Alkaline Salts and Urea in Convalescence.

A very careful investigation has been made by Dr. E. Salkowski (*Virchow's Arch.* lxxxviii. p. 391), who for a period of five weeks noted the period of convalescence in a patient recovering from typhoid fever. Dr. E. S. has published in tabular form the results observed. He found that the system does not commence to absorb a larger percentage of the albuminous part of food till about two weeks after the last increase of temperature; *i. e.*, not till that period he noted in the excrements examined the lacking of the albuminous parts of the food administered. Synchronously during convalescence a large percentage of potash-salts are taken from the food by the organism. It is a new fact, established by these researches, that the absorption of the larger part of potash-salts from the food takes place in a far earlier period of convalescence than that of nitrogenous substances: either therefore the tissue must lose decidedly during the febrile period potash-salts, which is hardly probable, or during convalescence the organism collects and keeps in reserve these salts before the new formation of tissues begins in a greater degree. We find herewith explained the fact, that so many convalescents from febrile diseases, we might say all, have a peculiar appetite for salty food. In Germany this is recognized so well that it is a rule to give such persons salt-sardelles for their breakfast. The patients relish them greatly.

Bleeding to Death of Fetus During Parturition.

Dr. Valenta reports (*Betz's Memorabilien*) a case where bleeding to death of the fetus took place during parturition, through a rent in the umbilical vessels, which crossed transversely over the os. A woman was delivered of her second child at full term. The mother stated that before the labor pains began the waters broke, and from that time up to the completion of labor, which was of ten hours' duration, she had a continuous discharge of blood. At no time was the stream observed by the attendants to be of a pumping character. On examining the after-birth, it was found to be about six inches in diameter, situated high up in utero. The umbilical vessels were given off from its lower margin; and before uniting to form the cord, they ramified in the surface of the chorion for about four and one-half inches. The cord measured sixteen and one-half inches. There were four veins passing from the placenta, which soon united to form two venous trunks, one of which, the smaller, arched outward before uniting with its fellow to form one umbilical vein. At the point of junction, and at a small distance from it, were two rents. The two arteries united to form one trunk on piercing the chorion, which immediately gave off a small branch that coursed along with the above-mentioned smaller veins. This was also torn across. This case shows clearly the necessity of examining the placenta in any case where death of the fetus has occurred.

Ozonized Air as a Hypnotic.

Professor Binz, of Bonn, gives a second contribution on Ozonized Air as a Hypnotic, in the *Berliner Klin. Woch.*, No. 43. The observations, which certainly do not seem encouraging, were made on doctors and medical students. The results were various. Several times the breathing of the ozonized air seemed to induce sound sleep; in other cases the effect in the same direction was less marked; in others, again, symptoms of depression were experienced; in one there was twitching of the muscles about the eyes and forehead; lastly, in some there was no effect on the cerebral functions. In most cases a feeling as of being able to respire more easily was felt. Binz therefore recommends this treatment in some forms of asthma.

Tetanus—Recovery.

Mr. Berger was called upon to treat a man who had received a gun-shot wound of the hand, and in whom tetanus fully declared itself on the eighth day. The contractions were very violent and pro-

longed. Disarticulation of the elbow was immediately performed, and the patient was put under the chloral treatment, of which, through the mouth and in enemata, he took three drachms daily. Immediately the operation was performed the spasms diminished in intensity, and in a week all symptoms of tetanus disappeared. * M. Berger believed that chloral alone is not sufficient to arrest traumatic tetanus, but combined with the amputation of the member it succeeds very well.

Camphor Enema.

In the *Gaz. Hebdom.*, Mr. Vigier states that camphor may be perfectly suspended, and become easily divisible, by the following formula: Camphor 15 grains, gum arabic 30 grains, one yolk of an egg, and 2 ounces of decoction of linseed.

CORRESPONDENCE.**A Case of Epilepsy Cured by Removing a Diseased Knee Joint.**

ED. MED. AND SURG. REPORTER:—

In June last I was called to attend Clifford A., a young man of nineteen and of strumous habit. I found him somewhat reduced in flesh and his principal trouble he thought was in his right knee, which was paining him severely.

I found upon examination that he was suffering with arthritis of right knee joint. The soft tissues were hypertrophied and degenerative changes had already taken place, although the stage of ulceration had not yet been reached. Upon inquiry of my patient and his mother, who is an intelligent woman, I found about the following history: About five years before while at school he received an injury of the right knee, and as near as I could learn synovitis resulted, and following this the tissues of the joint became the seat of a chronic inflammation. It was not until a year after the injury, however, that any noticeable change in the bones of the joint had occurred. But when first examined by me the bones of the joint were greatly hypertrophied, and as I afterward found this enlargement was due to a fungoid or spongy growth of the epiphyses and articular surfaces of the upper end of the tibia and lower extremity of the femur. There was complete ankylosis also. His history also showed him to be an epileptic, his first seizure dating about four years ago, or one year after the injury to the knee. The "Aura Epileptica" was very feeble in this case and could not always be felt, but when it was perceived it seemed to start from the diseased joint. Then also this joint seemed to be the first attacked when a seizure came on him, and was affected with the most violent contractions. I finally came to the conclusion that possibly that diseased joint was producing peripheral irritation of nerves there, and that this was the cause of the epilepsy. I was satisfied the only thing that could save the young man's life was an amputation, but the general condition of the patient's health made an operation of that magnitude out of all question at that time.

I consequently put him on a course of general treatment, using the co. syrup hypophosphites freely. I did not know that the operation proposed would relieve the tendency to epilepsy, but although I hoped it would, I gave no promise of such a result. His general condition gradually improved, but the affected knee as gradually grew worse; and a month after my first visit I detected fluctuation and other evidences of pus on the posterior and inner surface and a little above the joint. I opened freely, and got an abundant discharge of unhealthy-looking pus. The discharge gradually lessened but never entirely ceased until the latter part of August, when the disintegration of the soft tissues on the inner side of the joint had gone on so far as to almost leave the bones of the joint without a covering there. His general health did not seem at all affected by this condition. Indeed, he seemed so well that I thought it inadvisable to put the operation off longer. Nothing could be done however until his mother's return from Kansas, where she had gone on a visit. Unfortunately for us she was taken sick there, and did not return until the first of November.

At that time I found my patient in about the following condition: Pulse, 100; temperature, $99\frac{1}{2}^{\circ}$; general condition not so good as six weeks ago. The soft tissues on the inside of the joint almost all sloughed off. On the posterior surface of lower third of the thigh are four or five sinuses, through which, by means of a probe, the peculiar grating, sandstone feel of necrosed bone can be detected. The discharge from these sinuses is thin and ichorous, characteristic of necrosis. His epilepsy has gradually grown worse, until now he has from one to three seizures every week. It was now certainly a most unpromising case, but he and his friends were anxious for an operation. I knew nothing else could avail anything, and could give only an unfavorable prognosis for that procedure now. I, however, concluded to do the operation, and on November 3, assisted by Drs. Culverson and Knapp, of this city, and Drs. Kersey and Couch, of Stuart, I did so. I did the lateral flap operation, and found it necessary then to amputate at junction of middle and upper third of the femur in order to get healthy tissue for flaps. The patient rallied from the shock of the operation slowly, but very satisfactorily. I put him on anti-pyæmic and supporting treatment, consisting of quinine in tonic doses, stimulants, milk, eggs, beef, etc. There was no tendency to pyæmia, although during the first week suppuration was excessive. His temperature ranged from $97\frac{1}{2}^{\circ}$ to 100° , and pulse from 84 to 112. After the first week the wound healed rapidly. Nothing unusual occurred in the subsequent history of the case. And in spite of a strumous diathesis and debilitated condition, he made an easy and rapid recovery, somewhat to my own surprise and contrary to the freely-expressed opinions of many who saw or heard of the case previous to or after the operation.

One of the most remarkable features of the case, however, is the fact that he has had no epileptic seizure since the day of the operation, now nearly six weeks ago—a longer interval than has passed between any two seizures during the past two years and a half. I am not sanguine of the complete cure of this latter trouble. The operation was not performed with that object in view, but it

has just come up as an incident of the operation, and seems to be one of its gratifying results. I know of no parallel case, but cannot see why if we have cutaneous or other irritation of the peripheral termination of nerves as a cause of epilepsy, that when that cause is removed, the epilepsy would not also be removed, unless the "status epilepticus" is firmly established. And as the epilepsy in this case has continued for so long a period—four years—I am far from confident of permanent relief for my patient from this distressing disease. However, the other results of the operation, which are permanent, quite repay him for the pain and other inconveniences he has endured as necessary attendants upon an operation of such magnitude. W. C. CARRELL.

Greenfield, Ia., December 8, 1882.

(So short a time having elapsed since the operation, leaves considerable doubt, as our correspondent justly observes, as to the curative influence of the operation. But since there seems to be much reason for the relation of cause and effect that he suggests, we would be glad to hear more of this case later.—Ed.)

NEWS AND MISCELLANY.

Petrified Corpses.

From the *Medical Gazette* we learn that every corpse that is taken to the Paris morgue is now quickly converted into a block almost as hard as stone. This result is obtained by Carre's chemical refrigerator, which is capable of reducing the temperature of the conservatory, where each body is laid out on something closely resembling a camp bedstead in stone, to 15° below zero centigrade. At the back of this room is a row of stove-like compartments in which the corpses are boxed up and frozen hard before being exposed to public view. As an illustration of the intense cold thus artificially secured, a Paris journalist, in describing a recent visit to the morgue, says that in opening one of the compartments the attendant took the precaution to wear a glove, lest "his hand should be burnt by contact with the cold iron." The corpse which was taken out of its receptacle had been there for nine hours. The doctor who accompanied the visitor struck the dead man on the breast with a stick, and the sound was just as if he had struck a stone.

Handsome Donation.

The extensive medical works and library of the late Dr. Isaac B. Milford are now in possession of the Camden Medical Society, he having bequeathed them to that society. It embraces many valuable works.

The Causes and Prevention of Blindness.

The Fifth International Congress of Hygiene, which will meet at the Hague, Holland, in 1884, will award the prize of £80 offered by the London Society for the Prevention of Blindness to the author of the best essay written in English, French, German, or Italian, on "The Causes of Blindness and the practical means of preventing it." Besides this prize, the International Society for the

Improvement of the Condition of the Blind reserves to itself the right to award a second prize of £40, or two prizes of £20 each, and a silver gilt medal with a diploma, should it see fit, to such of the essays as should, in the opinion of the international jury for the principal prize, be deserving of it; the last-mentioned prizes will be distributed at the centenary festival of the first blind institution founded by Haüy, which will take place in Paris in 1884.

Physical Exercises.

Dr. Charles Cathcart, Lecturer on Anatomy in the Edinburgh School of Medicine, in a lecture delivered at the Edinburgh Health Society a short time since, gave, as to the effects of exercise in expanding the chest, some striking facts which related to a school where physical exercises had been systematically carried out. The effect of regular exercise was shown as follows: New boys, aged fourteen, average chest measurement, 29·3; at fifteen, 30·16; at sixteen, 32·0; at seventeen, 32·6; and at eighteen, 32·5; while former boys measured respectively 30·6, 32·1, 34·2, 35·8, and 36·8.

The Latest Sanitary Association.

"The Westminster Sanitary Association" of London, has for its object the prevention of the spread of infectious diseases in the midst of a dense population. At a meeting recently held under the presidency of Cardinal Manning, it was reported, after four months' experience, that signal success had attended the labors of the members. It was stated that in thirty-two families in which scarlet fever had broken out, the malady had been confined to one case in each. The latest and most approved methods of dealing with infectious cases are adopted, under the supervision of the visitors of the Association.

American Wet-Nurses Protected.

The treasury department has decided that a Chinese wet-nurse must be considered as a laborer, and as such is excluded from admission to the United States, under the provision of the act restricting Chinese immigration. This is a perfectly consistent decision. If there are good reasons to restrict the immigration of male Chinese labor, so are there to place the same embargo on the female. Wet-nursing is practically a labor, since the woman is pecuniarily rewarded for her work.

Items.

—Dr. A. D. Price, of Harrodsburg, Ky., President of the Kentucky State Medical Society, is a member of the Post-graduate class of the University of Pennsylvania.

—Dr. Corvisant, who was a devoted friend of Napoleon's and physician to the young Prince Imperial, has just died in Paris. He never recovered, it is said, from the shock caused by young Napoleon's death.

—Professor Virchow has in his laboratory at Berlin a collection of 6000 skulls, representing all races and times.

—The Mercer County, Pa., Medical Society are bringing action against all practitioners who have not complied with the law of registration.

—The local papers deny the statement that diphtheria is prevalent at Pittston, Pa.

OBITUARY NOTICE.

Dr. John G. Stetler, a well known physician of this city, died at his residence, 1218 Fairmount avenue, on Saturday, Dec. 30th, aged 60 years. He was born in Montgomery county, and graduated from the Pennsylvania College of Medicine in 1839, and a few years later established himself in the upper section of this city, where he remained up to his death. Owing to ill-health he ceased practicing a few years ago. His death was caused by an affection of the heart. He was a member of the County Medical Society and one of its Board of Censors. He leaves two sons, one of whom is studying medicine.

QUERIES AND REPLIES.

Treatment of Diphtheria.

MESSES. EDITORS: I should like to ask the readers of the REPORTER who have had cases of Laryngeal and Tracheal Diphtheria, what treatment has been the most successful?

W. J. H., M. D., Ohio.

Ohioensis. The action of colleges in admitting and graduating students who do not attend their lectures is reproached by all honorable professional men.

Vaccinator, Mo. It is asserted that pyæmia can be produced by impure bovine virus. It looks possible; but we do not recall any published cases.

Subscriber. The *Quarterly Compendium* is now ready. The price per year is \$2.50; single numbers, 75 cents.

MARRIAGES.

DRYSDALE—COWTON.—On Wednesday evening, Dec. 20, at the Church of the Atoneinent, by the Rev. Charles E. Murray, Dr. W. Atlee Drysdale and Miss Virginia H. Cowton.

WEBB—BUCK.—December 14, 1882, at Cohocksink Presbyterian church, by the Rev. William Greenough, Lanphear W. Webb, M. D., and Miss Jennie V., daughter of James Buck, esq., all of Philadelphia.

HARWOOD—MARTIN.—At the residence of the bride's father, Daniel Averill, esq., on Wednesday, December 13, 1882, by Rev. Andrew F. Bigelow, W. H. Harwood, M. D., and Mrs. M. A. Martin, all of South Malone, Franklin co., N. Y.

SHAFFER—DAVIS.—At Cream Ridge, N. J., Thursday, December 7th, 1882, by the Rev. E. E. Moran, George W. Shaffer, M. D., of Philadelphia, and Lizzie H. Davis, of Cream Ridge.

TURNER—BURT.—In Bridgeport, Conn., Dec. 25, 1882, by the Rev. R. G. S. McNeille, D. D., Albert L. Turner, M. D., and Miss L. May Burt, both of Bridgeport.

DEATHS.

MEIGS.—In this city, on December 16, of pneumonia, Dr. John Forsyth Meigs, in the sixty-fifth year of his age.

KIRKSEY.—December 21st, 1882, at Dawson, Texas, of pneumonia, Mrs. A. W. Kirksey, wife of Dr. W. H. Kirksey, in the 37th year of her age.

FOX.—On the evening of the 25th instant, Geo. Fox, M. D., of Philadelphia, in the 77th year of his age. He was a well-known physician, and at one time enjoyed a large practice, but for a number of years had not been engaged in the active duties of his profession.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

 *A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts.,

PHILADELPHIA.

 We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from \$15 to \$30, according to the number of currents. 1337-1351

MEDICAL MISSIONS IN HEATHEN LANDS.

BY M. P. BARKER, M. D.,

Of Newcastle, Pa.

CHINA,

Compact, unique, isolated for thousands of years her territory embracing an area of more than a million square miles and holding a population according to a recent Imperial census of more than three hundred and sixty million, has been considered for centuries a field of vast interest to philanthropists.

The population is so dense, that in order to obtain subsistence it is necessary to cultivate every available inch of soil. Even the hills and mountain-sides are cultivated, where it is so steep that one would suppose that the seed could not be scattered excepting by birds.

Such economy is practiced in land-saving for agricultural purposes, that large numbers live in boats on the rivers. A recent writer said with reference to this density of population, that "in its expedients for squeezing existence into the smallest possible compass, the Chinese continent resembled the cabin of a ship."

In consequence of this density of population and the utter ignorance of sanitary laws, combined with their filthy habits, is it any wonder that pestilence so often devastates the land? To the average citizen of civilized lands, whose motto is *progress*, the loyal adherence of these "machine men" to ancestral customs and ancestral rites is marvellous. "No progress" has been their

motto—the result of the demoralizing influence of idolatry, which has hung like a pall over their minds for centuries, reducing them to the most abject slavery. Bound with the fetters of ignorance, they have not until recently shown even a desire for improvement. Images abound everywhere. "Their temples, houses, streets, roads, hills, rivers, carriages, and ships, are full of idols. Every room, niche, corner, door, and window, is plastered with charms, amulets, and emblems of idolatry."

For centuries persevering efforts have been made by philanthropists to obtain a foothold, to arouse them from their sluggish, indolent, contented condition, and to awaken in their minds the spirit of inquiry and of progress, and to induce them to shake off the fetters which bound them and accept a higher type of civilization. But these efforts were generally unsuccessful. Their gates were closed against foreigners and foreign intercourse—their chief desire being to be let alone.

The medical profession, however, succeeded in gaining a foothold, prior to any treaty of commerce, or to any imperial edict permitting residence to foreigners in the empire.

Early in the nineteenth century a new era in the theory and practice of medicine dawned upon this benighted land.

The aim of those who inaugurated this new departure was to supplant their false beliefs and practices with a system of medical knowledge based upon scientific truth. The result of these efforts I will now attempt briefly to relate.

Dr. Pearson, who was in the service of the East India Company, in Canton, in 1805, introduced

VACCINATION,

and watched its progress in native hands until he felt that its success was assured.

A recent writer in referring to the results of Dr. Pearson's effort, stated that the people were about as well protected as in any country where vaccination was not compulsory. This was a grand victory—the first step in the line of progress.

The fact that those who were vaccinated received immunity from this loathsome, virulent disease by so simple a remedy, was an object lesson of immense value. It would teach them that Western medical knowledge was immensely superior to their own superstitions, beliefs and practices, and also to the boasted power of their gods. It would also teach them that being in error in one thing, they might be also in many others, and thus be the means of opening the way for receiving treatment for other affections.

In 1827, Dr. T. R. Colledge, who was also in the employ of the East India Company, established a

DISPENSARY

in Macao, ninety miles south of Canton. During a residence of four years, he treated six thousand cases. His success, both as physician and surgeon, especially in the treatment of diseases of the eye, produced "a great sensation, and prepared the way for medical missionaries from England and America."

In 1834 Rev. Peter Parker, M. D., reached China and settled in Canton. He was the

PIONEER MEDICAL MISSIONARY,

from America to China. When he arrived at his destination, the gates were not yet open to foreign intercourse and commerce, and missionary work was still under the ban of the government.

Nevertheless he succeeded in gaining permission to open a hospital in Canton. It had not been open long until patients flocked to it by hundreds "and the street, was filled with waiting crowds, and some of whom even passed the night there, to be ready to enter the next morning."

The second medical missionary was Dr. William Lockhart, who went in 1838, and was followed the next year by Dr. Benjamin Dobson. Both of them were from England, Dr. Lockhart being the pioneer from that country.

The labors of these medical pioneers were not limited merely to the practice of their profession, or to the establishing of hospitals, though they were by no means neglected. Taking a comprehensive view of this vast field, "already white to the harvest," they set about, at once, to

inaugurate measures to uproot their superstitious theories and practices, and prepare the way, for the introduction of a knowledge of Western medicine and surgery.

In conjunction with Robert Jardine, M. D., of the firm of "Jardine, Matheson & Co.," they formed a

MEDICAL MISSIONARY SOCIETY IN CHINA,

the object of which was, not only to support the hospital, but to induce physicians to come to China and join them in their philanthropic enterprise. Dr. Colledge was the first president of this society, a position which he still held in 1876. This society was organized in 1838, and is said to be still in existence.

They issued a circular, setting forth the needs of this vast multitude of human beings, and appealed with tender pathos to their medical brothers in enlightened lands, for aid in this gigantic enterprise, so that they might be enabled to transmit to unborn millions, blessings the value of which,

GOD'S ARITHMETIC ALONE COULD COMPUTE.

A few extracts from this circular cannot be otherwise than interesting to physicians. I will therefore give a few quotations. It says, "It is affecting to contemplate this Empire, embracing three hundred and sixty millions of souls, where all the light of true science is unknown, where Christianity has scarcely shed a genial ray, and where the theories of matter and mind, creation and providence, are wholly destitute of truth. It is deeply affecting to see the multitudes who are suffering under maladies from which the hand of charity is able to relieve them. * * * * In the vast conflict which is to revolutionize the intellectual and moral world, we may not underrate the value of any weapon.

"As a means, then, to awaken the dormant mind of China, may we not place a high value on medical truth, and seek its introduction with a good hope of its becoming the handmaid of religious truth? If an inquiry after truth on any subject is elicited, is there not a great point gained? And that inquiry after medical truth may be provoked, there is good reason to expect; for as exclusive as China is, in all her systems, she cannot exclude disease, nor shut up her people from a desire for relief."

In another address we find the following: "To restore health, to ease pain, or in any way to diminish the sum of human misery, forms an object worthy of the philanthropist. But in the prosecution of our views, we look forward to far

higher results than the mere relief of human suffering. We hope our endeavors will tend to break down the walls of prejudice and of long cherished nationality of feeling, and to teach the Chinese that those whom they affect to despise, are both able and willing to become their benefactors. * * * * In the way of doing them good our opportunities are few, but among them that of practicing medicine and surgery stands pre-eminent. * * * In the department of benevolence to which our attention is now turned, purity and disinterestedness of motive are more clearly evinced than in any other; they appear unmasked, they attract the gaze and excite the admiration of thousands."

The influence of these men was not limited to the cities, nor to the provinces in which they labored, nor even to China, but it extended also to other heathen lands.

In 1840, war having broken out between England and China, Dr. Parker returned to the United States, where he spent the greater part of his time in lecturing on this interesting and important topic. He also visited England and Scotland, where his lectures excited much interest.

I shall here leave Dr. Parker for the present, and call attention to another

NEW ERA JUST DAWNING

upon China, which was destined to accomplish more in the line of progress and for the destruction of her effete systems of religion, moral science, and medical knowledge, than had ever before been accomplished in her history. About two centuries prior to this, the Italian Jesuit Valignano, when on his way to Japan, halted at Macao. Casting a wistful look across to the rock-bound coast of China, he exclaimed:

"O, ROCK, ROCK, WHEN WILT THOU OPEN."

But the "rock" has opened. The gates of China stand ajar, and citizens of other nations can now enter.

By the treaty of 1842, five ports were opened to foreign residents and foreign commerce. These ports were Canton, Amoy, Foo-Chow, Ning-po, and Shanghai. Hong Kong was ceded to Great Britain.

Immediately after the opening of these ports there was a rapid influx of philanthropic toilers. The auspicious time—the time long and anxiously looked for—had come at last; and many buckled on their armor, determined to redeem China from her thralldom. Among the medical men were two Americans, viz.: Dr. D. J. McGowan and Dr. D. B. McCartee. Both of them located in Ning-po and conducted hospitals.

In 1843, Dr. Parker returned to Canton, reopened the hospital, and conducted it until 1855, when he returned to the United States.

From the time of his return until his final departure, over 53,000 patients were treated; besides a large number of surgical operations were performed, such as lithotomy, the removal of tumors, amputations, etc., "which excited the wonder and admiration of the people at the daring and skill of the foreign surgeons; and they now learned that those whom they despised as outside barbarians had means of removing dreadful deformities and of curing most painful diseases."

Upon the resignation of Dr. Parker, the superintendency of the hospital was transferred to Dr. J. G. Kerr, who was the historian of a large portion of the facts to which I have referred. In 1876—having then had charge of this hospital over twenty years—he reported "11,000 in-patients treated, and many thousands of out-patients applied for relief."

The statistics of surgical operations performed during this time showed 345 cases of lithotomy, 87 of lithotrity, 50 of urethral calculi, 18 of preputial calculi, 433 tumors excised, 261 for necrosis, 500 for cataract, 93 for artificial pupil; fistula in ano, 80; circumcision, 116.

Dr. Kerr is still the superintendent of this hospital. His report for last year showed that there had been 20,396 patients treated, and 1,115 surgical operations performed, and that new blocks of wards had been added to the hospital.

In addition to the care of the hospital, he, with two assistants, was engaged in giving instruction to a large medical class.

In 1861, Dr. Lockhart, under the protection of the British Embassy, opened a hospital in

PEKING, THE IMPERIAL CITY.

In 1864, it was transferred to Dr. J. Dudgeon, Dr. Lockhart returning to England. "High mandarins, eunuchs of the palace, princes of the blood, Mongolian princes and princesses," are said to have resorted to it for treatment.

A university was established in this city, and Dr. J. Dudgeon was appointed lecturer on

ANATOMY AND PHYSIOLOGY.

This was a very important event, as it shows the world *does move, even in China*.

It would require too much space in an article such as this to enter into further detail of individual hospitals, as those already mentioned are typical of others. It will be sufficient to say that hospitals multiplied rapidly in other cities, and that they are doing good work. They can be

found in Swatow, Amoy, Foo-Chow, Chifoo, and Tientsin, Hang-Chow, Kiu-Kiang, and Hankow—all large cities. In these hospitals all manner of diseases are treated. Capital surgical operations are performed, as well as those of minor importance, and they are resorted to by "high officials of the Empire, as well as people of the lower and middle classes."

Marvellous as it may seem, in view of the hostility of the people to the foreign physician and surgeon but a few years ago, a revolution has been accomplished in this great Empire, and the

HOSPITAL IS NOW RECOGNIZED

as an *established institution*.

In the achievement of these great results, an appalling amount of labor has been performed. Outside of private practice, establishing and conducting hospitals, a large amount of other work has been performed by these diligent, devoted men. A large number of medical classes have received instruction, and at the present time there are many native physicians engaged in private and lucrative practice. Kwan To, whom Dr. Parker educated in the Canton hospital, became quite famous as a surgeon. He died a few years ago, after having accumulated a large fortune.

The preparation and translation of text-books was also an important feature of medical missionary work. A modern text-book in any of the branches of medical science was not to be found in the Empire. Dr. Benjamin Dobson was the pioneer in this department of work. His first work was on Anatomy and Physiology. This was followed by one on the "Principles and Practice of Surgery," and another on the "Practice of Medicine and Midwifery."

Dr. Lockhart said with reference to these works, "The volumes thus published will be of incalculable benefit to the Chinese; and were this all that Dr. Hobson had done, it would be worth the labor of a lifetime." Many works followed these, by different authors, and it is probable that by this time the Chinese language contains a well-prepared system of medical knowledge—the product of European and American physicians.

At present, there are twenty-five foreign medical missionaries in China, nine of whom are females. But what are they among such a population? To the enthusiast in the profession, there are *glorious opportunities*, and in private practice *golden rewards*.

—Small-pox is prevalent among the rag sorters in the mills of Conshohocken.

NOTES FROM CASES IN PRACTICE.

BY J. B. R. PURNELL, M. D.

Of Snow Hill, Md.

Aloes.—This useful medicine will not cause hemorrhoids, as stated by some authors. It often tends to alleviate or cure that disease when properly combined with an alkali, as soda bicarb. or lithia carbonate. It will act on the upper as well as lower intestines, notwithstanding the contrary statement in some of the works. To prevent any unpleasant effect, add alkali and a little aromatic, and, when requisite, hyoscyamus extract. Aloin, the active principle of aloes, is effective in 1-4 or 1-5 the quantity of that substance, and I am confident it is the best cathartic ever discovered when properly prepared, even as a cholagogue excelling hydrarg. chlor. mite in the great majority of cases. It should have a deep yellow color, also an intensely bitter taste, which, however, can be disguised with extract glycyrrh. and soda bicarbonate.

A short time before his decease, Gov. Henry A. Wise said to the writer, "You doctors say aloes will produce piles, but I tell you it will cure them." I in substance replied that his statement accorded with my own experience.

Sugar in Dyspepsia.—I have for many years been using pure sugar in some forms of dyspepsia. Though often beneficial when employed *alone* either in sick-headache or in migraine attended with vomiting or nausea or a tendency thereto, the following combinations will in some cases be found of great value:

R. Sacch. albi, 3 i-ij.
Zingiberis, gr. v.
Sodii chlor., gr. v-x. M.

R. Sacch. alb., 3 i-ij.
Capsici, gr. iij,-vi. M.

S. To be taken alone or with but little water.

I report the following case for the reason that the operation of *trephining* is seldom performed at that age, *i. e.*, on one so young: in my case-book I find several pages pertaining to it, but will here give only a brief extract:

March 19, 1879, Willie Walls, a bright child, æt. 6½ years, was struck on the top of the head with the sharp edge of a slate, the consequence of which was a small, narrow scalp wound and a fracture of the os frontis, about an inch and a half to the left of the longitudinal sinus or mesial line. Dr. Marshall, who was quickly summoned, observed the following condition: Feeble pulse, convulsions, insensibility. Three or four hours after the occurrence, I saw the case with Dr. M.

and noticed the following symptoms: Pulse *extremely frequent* (I mean *frequent*, not *slow*) and compressible, pupils dilated, iris immovable by light, total unconsciousness, convulsive movements of arms and hands. We concurred that life was in imminent peril, the patient being apparently in articulo mortis. Having my trephining instrument case with me, no time was lost in preparation for an operation. Before trephining, I succeeded in removing a partially detached small piece of bone at the site of fracture, though without giving any relief. First making crucial incisions of the scalp, and dissecting back the flaps—of the two instruments (trephines) I applied the smaller to the left of the wound, removing not less than three-fourths of a circle of bone a little larger than a dime, leaving an opening adjacent to and in direct communication with the wound. All convulsive action ceased at once, the pulse rapidly improved, consciousness returned by degrees, the life of the little patient was saved. It is unnecessary to speak of subsequent treatment—it will suffice to say a speedy recovery was made.

The following singular and rare case occurred in my practice:

Mrs. B., now aet. 52, married, having had only one child, aet. 27, at times between 1860 and 1869 had symptoms as follows:

Apparently tenderness in region of uterus and vagina, specially at the os uteri, with other symptoms of hysteria. No fever; at times, in some of the attacks, with the other symptoms there was great distention, accompanied with pain all over the abdomen, the tumefaction with *resonance* extending even to the *chest* and *nearly* as far as the *neck*; also *ischuria renalis* (entire suppression), percussion, and the catheter frequently introduced revealing the fact that the bladder was empty—continuing for several days (once or twice about a week) *without fever* and *without coma* or any phenomenon indicative of danger; this last condition occurring sometimes with, at other times without, the symptoms previously mentioned. In some (not all) attacks the ischuria was accompanied with discharges of mucus and purulent fluid from the bladder in small quantity; the distention in the thoracic abdominal region, usually continuing from 12 to 24 hours, several times disappeared within fifteen minutes under the use of an anæsthetic freely inhaled (chlorof. 1 part, ether 2 parts) and did not recur for a day or at least for several hours, generally leaving the patient free from pain; nevertheless there was tympanites and not muscular rigidity. Anodynes, liniments, etc., over the uterus, and

occasionally aperients, were used in the treatment. Diuretics were of no avail.

(To be continued.)

A CASE OF GANGRENA ORIS.

BY D. A. HENGST, M. D., OF PITTSBURGH, PA.

On July 28, 1882, I was called to see Mary N. White, two years of age, with the following history: She had just recovered from a moderately severe attack of measles, and now had a swollen, pale face, œdema about both eyes, but the swelling was hard and painful over both parotid and submaxillary glands, and of a shining, glistening appearance; the mucous membrane of the mouth was also swollen and inflamed. Her surroundings were those of poverty and filth, and she had the appearance of an ill-nourished and badly-fed child. Her general condition was bad—pulse 120, temperature about 102°, tongue coated, had some diarrhœa, and was very restless and irritable. The next day the swelling had become more marked. She had indurated patches on the scalp over left parietal bone, at the occiput; over the glands of the face, on lower lip, and on the upper border of the sternum. About two days after this, eschars formed over all these indurated spots as well as on the mucous membrane of the mouth at a point opposite the last molar tooth on each side. In about one week after my first visit these eschars had sloughed away, leaving deep ulcers, which continued to spread in width and depth until in some of them all the soft tissues were destroyed to the bone. She now presented a most pitiable appearance. On the scalp were two large ulcers about the size of a silver dollar, exposing the bone over its entire base; in a short time the narrow bridge of tissue between them was eaten away, thus exposing almost the entire left parietal bone; back of this, over the occiput, was another extending to the bone and about one inch in diameter. Over both parotid glands were deep ulcers from an inch to an inch and a half in diameter, and of a circular shape. A large section of the lower lip had sloughed away, making it appear like a harelip, and causing considerable difficulty in deglutition. The ulcer on the upper border of the sternum, about three-fourths of an inch in diameter, was the most destructive one, for at the time of her death it had ulcerated its way into the pleural cavity. All of these ulcers had tough and sharply-defined edges, with no inflammatory areola. Those on the inside of the mouth were not as deep or destructive as the external ones. Her general condition now was very

bad. Pulse very rapid, high fever every day, with diarrhoea and cough. She continued in this condition until the 23d day of August, when a severe convulsion caused her death.

As regards treatment, when the case was first seen it looked like one of erysipelas of the face, and I prescribed accordingly; but as soon as the eschars formed I began to suspect the terrible nature of the disease I had to deal with. Then applied strong nitric acid as a cauterant and alterative; repeated this at various times, and afterwards used a paste of carbolized water; but these applications would not check the spreading tendency of the disease, nor change the character of the ulcers.

Internally she was given morphine when needed to calm irritability. Tr. Ferri Chlor., Quinia and stimulants, also nutritious food, such as beef tea, milk, etc. This has been to me a very interesting as well as an extremely rare disease, being the first case of the kind in a practice of thirteen years. The slow progress of the disease, and its not affecting the mouth as much as the tissues on the outside, might be brought forward as an argument against gangrene of the mouth. But the course of the disease is not always so rapid. In consulting the authorities upon this subject, I find it described as being extremely rare in private practice, but more frequent in hospitals for children; that unfavorable hygienic conditions constitute a predisposing cause, and that it almost always follows upon some acute or chronic disease, especially measles. In this case the hygienic surroundings were extremely bad, and it followed an attack of measles. M. Barou says he has never known it to occur as an idiopathic disease, and that it is questioned whether or not large and continued doses of mercury have ever produced it.

RADICAL CURE OF POPLITEAL ANEURISM.

BY S. PIXLEY, M. D.,
Of Peninsula, Ohio.

Arthur Seeley, twenty-four years of age, single, on the 1st of January, 1882, came to me for medical advice. My diagnosis was Popliteal Aneurism. The following facts were elicited: Some eight years ago he had a pair of shears penetrate the popliteal space of his left leg, which confined him to bed for two weeks, soon after which he recovered the use of his leg. Some three years previous to the first of February, 1882, he complained of stiffness of the knee, and a small tumor in the popliteal space. Upon examination, I advised him to con-

sult the professors of the Cleveland City Hospital for treatment.

He entered the hospital on the 21st of February, 1882, and his treatment while there was as follows: First by flexion of the leg upon the thigh, bound by bandages, his heels touching his nates, in which position he was kept for three weeks, his suffering being allayed by morphine, administered hypodermically. There was no improvement of the aneurism. The bandages were removed on the 14th of March, and an attempt was made to straighten the leg, which stood at nearly right-angles with the femur.

The leg was raised and placed in an extension sling. An India-rubber bandage was then applied from the calf of the leg to the lower portion of the middle third of the femur three days, when the swelling and pain of the foot required the removal of the bandage and the re-application of it from the toes to the middle third of the femur.

This treatment was continued until the 4th of April, when he was discharged from the hospital without relief.

The patient returned to this place to have the artery ligated.

On the 11th of April I procured the assistance of Doctors Humphry, Cole and Humphry to assist me in an attempt to make a radical cure by digital pressure.

At nine of same day we began digital pressure, and continued same for twelve hours, then left patient to rest for thirty-six hours. Again resumed pressure for six hours, at which time pulsation entirely ceased through the aneurism. We still continued pressure for three hours, when we considered the cure effected, which has proved itself permanent.

On July 1st the tumor was almost obliterated, and the patient resumed his usual work, and has continued well up to this date, Dec. 8, 1882.

HOSPITAL REPORTS.

Amyloid Degeneration of the Liver.

BY FRANK O. NAGLE, M. D.,
Professor of Materia Medica, Therapeutics and Clinical
Medicine in the Medico-Chirurgical College,
Philadelphia.

Reported by ALBERT KOLB.

GENTLEMEN: This boy comes before us to-day suffering from a disease rather unusual for one of his age. I shall first read you his history as obtained from his mother, who is here with him.

History: Harry Gayant, age 6 years 7 months. Father and mother are both living and healthy.

Harry is the second child from the second husband. From his birth until two years ago last June he was perfectly well; he then contracted measles in a mild form, from which he recovered without any treatment, excepting confinement to bed, until convalescence was established. Shortly after his recovery, his mother noticed an offensive discharge coming from the left ear, which gradually increased in quantity, and continued to be horribly offensive. This discharge (which was probably due to caries of bones of the ear) continued for at least (6) six months, when it gradually ceased. About this time his mother noticed some slight puffiness (oedema) of the feet, which lasted several days, and at the same time she also noticed his abdomen enlarging; this enlargement commenced in or near the epigastrium, and gradually but steadily grew larger until it has reached its present enormous size. Pain was never associated with the swelling, nor was there at any time jaundice.

Appetite has always been good, but "food did not seem to nourish him," emaciation gradually taking place, particularly in the arms and legs. Bronchorrhœa with fetid expectoration has been a constant symptom, together with noticeable dyspnoea from time to time. Urine has always been freely discharged. He was also liable to occasional attacks of diarrhœa.

Now gentlemen, when a patient comes to you for the first time, ask him his name, age, occupation, etc. etc., and then you proceed to examine him in order to arrive at a diagnosis. In all cases it is not necessary to follow strictly the regular form for examining patients as laid down in your text books. Take the most prominent symptom of which he complains, and let that serve as your starting point in your examination: *i. e.* if he complains of cough, you proceed at once to examine his lungs; oedema of the feet will refer you to either the heart, kidneys or liver, etc., etc. By so doing you will be able to save much valuable time.

I shall follow this rule in the present examination. This boy comes to us presenting a very prominent symptom of his complaint, which I shall take as a starting-point in making my diagnosis. You notice his abdomen is considerably enlarged. I shall examine into his present physical condition, and see as to the cause of this enlargement.

His countenance, you notice, is sallow, anæmic, unhealthy in appearance, showing that the child must be suffering from some grave constitutional cachexia.

Measurement around abdomen at the point of greatest swelling, above the line of the umbilicus, 26½ inches.

The superficial veins of the abdomen are everywhere enlarged, not however to a very considerable degree.

On palpation the abdominal walls are tense as if they were unduly stretched. Percussion, commencing at the pubes and passing upwards towards the sternum, in the middle line of abdomen, gives tympanitic resonance to a point one inch above the umbilicus. In the left inguinal region same percussion-note up to the left hypochondriac region, where, posteriorly, splenic dulness commences. In the right inguinal region same

resonance, dulness beginning opposite crest of ilium.

This swelling does not change its shape or position with the changes of the patient's body.

The liver dulness, on the right side, extends from the (6) sixth rib downwards to the crest of the ilium—from xyphoid cartilage to within one inch of umbilicus. Left lobe fills up left hypochondriac region. With a little care I can map out the entire organ, showing you its characteristic shape is preserved. The edges are sharply defined and can be readily felt through the walls of the abdomen.

The area of splenic dulness extends over four inches longitudinally.

Heart is somewhat enlarged, with a systolic, probably anæmic, murmur at the apex.

On auscultation moist rales are heard, anteriorly, over the apices of the lungs and posteriorly between the shoulders over the larger bronchial tubes.

The urine contains trace of albumen, and an occasional hyaline cast is found. With these symptoms pointing to involvement of the kidneys, there is no dropsy.

What are the different causes which may give rise to enlargement of the abdomen, and what is the most probable cause in this case before us?

There are many diseases characterized by swelling of the abdomen. We have enlargements due to dropsy (ascites), over-distention of the bladder, tumors, tympanites, enlargements due to diseases of the solid abdominal viscera.

In ascites or hydroperitoneum, the fluid is found in the abdomen in the most dependent portions, and distends the abdomen from below upwards. This fluid changes with the different positions of the patient's body. On percussion we would have absolute flatness over the fluid and a peculiar impulse imparted to one hand placed on the abdomen when the latter is tapped with the other hand; this is known as the sense of fluctuation. In this case none of these symptoms are found; yet this boy has been treated by several regular physicians in this city for dropsy. By remembering these points, I am confident that none of you will make the same error.

Over-distention of the bladder sometimes occurs to such an extent as to give rise to enlargement of the abdomen. This occurs in stricture of the urethra and in the sacculated bladder sometimes met with. You would distinguish such a condition by almost the same physical signs you would have in ascites. Introduction of the catheter would establish your diagnosis.

Tumors, either benign or malignant, are not admissible in this case on account of the age of the patient.

Tympanites or an excessive distention of the intestines by gas occasions enlargement of the abdomen, giving rise to its characteristic tympanitic resonance. This occurs at times to an enormous degree in typhoid fever.

Enlargement of the solid abdominal viscera.—Ague-cake, or enlargement of the spleen occurs in persons having had malaria or who are living in malarious districts—the spleen in these cases being developed to such an extent that the gland fills up almost the entire abdomen. Although the spleen in this boy's case is somewhat enlarged, there is an entire absence in his history of malarial poisoning.

Enlargements of the liver.—There are several diseases of the liver in which enlargement of the organ is a prominent symptom. As our patient has never had any pain, I shall only consider the painless varieties of enlargement of the liver. These are fatty degeneration, hydatids, and amyloid degeneration of the liver.

In fatty degeneration of the liver the organ is usually moderately enlarged; the edges lose their characteristic sharpness and become round or blunted; the organ is less firm than normal. This occurs in persons suffering with chronic diseases, as tuberculosis, or of intemperate habits, or over-feeding, especially on articles of food containing a large percentage of fat. Jaundice may or may not be present. If ascites occurs, it is probably due to the accompanying cirrhosis.

Hydatids of the liver.—This affection is produced by the introduction of the ova of tape-worms into the alimentary canal; from there they make their entrance into the liver, etc., where they develop into cysts, varying in size from a small cyst to a tumor as large as a child's head. The tumor makes its appearance on the surface of the liver more frequently on the right side than the left. The patient complains of a sense of fullness or weight over the region of the liver. A peculiar fremitus, hydatid fremitus, is in some cases observed, and is highly characteristic when present.

The last disease of the liver characterized by enlargement, and not associated with pain, is amyloid degeneration. This affection occurs in persons who have been subjected to prolonged discharges, generally the result of caries of bones; in persons having constitutional disease, especially the scrofulous or syphilitic cachexia. The enlargement is uniform, the shape of the organ not being lost. The tumor is firm, and does not give rise to any pain on handling. The spleen is generally enlarged, and albumen in the urine shows that the kidneys are also similarly diseased.

I think you will all agree with me that the evidence I have produced points clearly to disease of the liver as the cause of the enlargement in this case before you.

It is not fatty degeneration of the liver, as the swelling is too great, the organ too firm, and the edges too well defined.

It cannot be hydatids of the liver, as the enlargement is too uniform, and also on account of the rarity of this affection in this country.

By exclusion, therefore, and from the fact that spleen and kidneys are also affected, together with the history of the case, we diagnose amyloid degeneration of the liver as the cause of this enlargement.

The exact nature of the pathology of amyloid degeneration is a point not yet satisfactorily solved. Amyloid, albuminoid, lardaceous, bacon-like, waxy, scrofulous enlargement (Budd), are names used synonymously; they apply either to the supposed nature of the affection, or to the peculiar appearance of the organs affected. The name amyloid was applied to this disease by Virchow, who supposed it to be a substance analogous to starch on account of the color produced by iodine.

It consists of a morbid infiltration into the tissue with a substance resembling albumen, having

its primary deposit in the muscular tunic of the capillaries or arterioles of the organ affected. The organ increases in size, and its functions are thereby impaired. This is met with in persons having been subjected to long-continued suppuration, especially due to bone disease, or empyema, chronic diseases of the lungs (tuberculosis), various ulcerations, etc. Any part of the body may be affected, although it is especially apt to occur in the liver, spleen and kidneys, which are generally simultaneously involved.

It is thought that the waxy deposit is dealcalized fibrin, as the system has been found deficient in them, especially in those cases where the disease follows copious suppuration, the alkalies being removed with the pus.

The most characteristic feature of the degeneration is the starch reaction when iodine is applied. If a solution of iodine is applied to healthy tissues a yellow color is produced. If the iodine is applied to an organ affected with amyloid degeneration it changes its color to a mahogany brown, which, after a while, disappears, and the part regains its former color. If, however, after applying the iodine solution a drop of sulphuric acid be carefully added, the color is changed to a bluish black or violet.

When this degeneration affects the liver, the organ increases in size. The enlargement is uniform. The characteristic shape of the liver is preserved. Its weight and density are also increased. These changes do not cause obstruction of the portal circulation, and consequently you do not have dropsy (ascites). The injury to the organ is in proportion to the amount of infiltration, and is caused by the overcrowding of the cells and tissues, and consequent interference with the circulation through the arterioles, producing loss of function of the organ.

This disease is rare in childhood and in old age. "Of sixty-eight cases analyzed by Frerichs, nineteen occurred between ten and twenty years, nineteen between twenty and thirty years, eighteen between thirty and fifty years, nine after the age of fifty, and only three prior to ten years."

Prognosis is unfavorable. The disease is incurable, though months and years may be required before a fatal termination takes place. Death occurs from the gradual exhaustion produced, or from the diseases with which it is generally associated.

Treatment.—For this disease there are no so-called specifics. Treat your patients upon general principles. In the majority of cases iron for the anæmia, and iodine for the constitutional cachexia giving rise to it, are the two drugs from which the most benefit has been derived. If syphilis is the cause of the cachexia, iodide of potassium is strongly indicated. The diarrhœa may be controlled by the vegetable astringents, bismuth subnit., and opium. For the cough, chloride of ammonium gr. ij. to v. every three or four hours. Chloride of ammonium in large doses (gr. x. to xxx.) three times a day is supposed to arrest the further development of the disease. Support the system with tonics; let quinine form the basis. Arsenic, strychnine, iron, and the vegetable bitters may be advantageously combined. Careful attention to diet. Plenty of eggs, milk, chicken, etc. Outdoor exercise when the weather permits.

During the course of this disease you are especially apt to have as complications diarrhoea, obstinate vomiting, albuminuria, dropsy, and uremia. These all require appropriate remedies.

For this boy I shall order

R. Syr. ferri iodidi	f. $\frac{3}{4}$ ss.
S. 5 drops 4 times a day.	
R. Ammon. chloridi.	gr. x. to viij.
Mist. glycyrrhiza co.	f. $\frac{3}{4}$ ij.
M.ft. mist.	
S. 3j. every 4 hours.	

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, December 14, 1882. The President, Dr. Jas. Tyson, in the chair.

A Case of Mitral Obstruction, with Sequential Lesions.

Exhibited by Dr. E. P. Bruen.

I submit this specimen because it favorably illustrates the lesion and the sequential changes in the different chambers of the heart. The auriculo-ventricular opening of the left heart is nearly occluded by an epiglottic-shaped enlargement of one of the leaflets of the mitral valve. The valve is very much thickened, and the focus of a considerable calcareous deposit. The orifice during life permitted a reflux of blood from the ventricle into the auricle. The left auricle is dilated and hypertrophied so that its cavity is about twice as large as normal. The right ventricle is very much dilated, the walls of this cavity are less than half the normal thickness, and the ventricle must have had during life twice its physiological capacity. The tricuspid valves were insufficient on account of the dilatation. The considerable enlargement of the left auricle and right ventricle occasioned during life a broadening of the area of dullness on the level of the third and fourth ribs, viz: the apex of the cardiac triangle. It also produced a decided increase in the area of the cardiac dullness to the right of the median line of the sternum. In children, the heart with similar enlargement encroaches upon the left pleural cavity to such an extent that the physiological inflation of the left lung cannot occur. Bronchial breathing is produced, audible posteriorly, while anteriorly, below the second interspace, no respiratory murmur is audible. In these cases, when the complication of bronchitis occurs, the physical signs suggest a pleural effusion. Enlargement of the right ventricle, both in children and adults, causes a pronounced impulse at the epigastrium, and occasions serious pain and inconvenience. The murmur heard during life in the case from which my specimen was taken indicated this lesion, both presystolic and systolic murmurs being audible. The second sound at the pulmonary artery cartilage was also much accentuated, owing to the repletion of that vessel with blood. The first sound over the right ventricle was very clear and distinct, as is common in these cases, but the first sound at the apex was obscured by the murmur. The patient, from whose body these specimens were removed, was a woman aged 45 years, who had

been subject to heart disease since twenty. The immediate cause of death was pulmonary repletion with blood, which induced right-heart failure. Compared with mitral regurgitation, this mode of death illustrates a feature of the chemical pathology of mitral obstruction. In mitral regurgitation death occurs with heart failure, but usually after serious dropsy. In mitral obstruction dropsy is not so prominent a symptom, but the pulmonary engorgement prevents a perfect supply of blood to the aorta. The right-ventricle failure in cases of mitral obstruction brings about death in the same manner as left-ventricle failure does in cases of aortic obstruction.

Pericardial Effusion and Adhesion of the Pericardium to the Apex of the Heart, Mistaken for Heart-Rupture.

Exhibited by Dr. J. T. Eskridge.

Dr. Eskridge said that in this case the physician making the autopsy actually considered the specimen to be one of heart rupture. The patient was an athletic young man, and perfectly well until a few days before he sought medical advice. He was under treatment for only 24 hours, suffering from cardiac pain and great prostration. He died suddenly and unexpectedly when no one was near him. The attending physician, who made the post-mortem examination with no professional assistance, reported effusion in both pleural cavities, the pericardium distended with thin, non-coagulated blood, and a rupture of the left ventricle. Dr. Eskridge said that a careful examination of the heart, pericardium, adjacent glands, and portions of the larger bronchi, showed marked evidences of pericarditis and pleuro-pericarditis. The pericardium was adherent to the lower third of the heart, but the adhesions were recent and easily severed. The heart was not much enlarged; its valves were nearly normal, and its muscle firm. No rupture was found. He believed that the case was one of pleurisy and pericarditis with effusion, death taking place suddenly from mechanical interference with the heart and lungs. He thought that the most plausible explanation of the doctor's mistake in calling it a case of cardiac-rupture was, that when severing the blood-vessels around the heart, blood flowed into the pericardium and mingled with the serous effusion. He did not think that a firm, non-fatty heart could rupture itself by its own contractions. If the pericardium was filled with effusion, in that instance it taught a lesson of far more practical value than a case of cardiac-rupture under similar circumstances would. It was evident if the pericardium should be attached to the apex of the heart in a case of pericardial effusion, in which operative interference was determined upon to free the heart's action, a thrust of the trocar into the pericardium would greatly endanger the ventricular walls.

Several Specimens of Eyes Enucleated on Account of Sympathetic Irritation in the Other Eye, or for Fear of its Developing.

Exhibited by Dr. Little.

Sympathetic irritation and sympathetic ophthalmia are the only two forms of the sympathetic diseases of the eye that afford an opportunity for

pathological study, and in these cases only the enucleated eye can be investigated; just what are the conditions in the eye protected by the enucleation of the other eye primarily at fault, must remain uninvestigated; if full restoration of the function of vision is attained in the one sought to be protected by the enucleation of the fellow-eye, great satisfaction only is felt. Less and less opportunity is being afforded of studying the condition of an eye enucleated for the presence of sympathetic ophthalmia in the other eye, since merely the sympathetic irritation of the sound eye impels the surgeon to enucleate the primarily affected eye before true sympathetic ophthalmia asserts itself. The portion of the eyeball which renders liable the development of this affection when diseased is so well known that not even sympathetic irritation should be allowed to develop, as an early enucleation will prevent it. Enucleation of the primarily diseased eye when true sympathetic ophthalmia is present in the other eye is now questionable, as after all inflammation has subsided under treatment, surgical procedures upon the primarily affected eye may afford the best results for visual purposes. A recent experience will bear me out in this statement: the patient refusing the advice of a former medical attendant and also my own, after two months suddenly developed sympathetic ophthalmia of the sound eye. Enucleation was then too late. Now both eyes are becoming quiet, and I am in doubt which in the end will be the more available eye. A physician recently under treatment for a severely traumatized eye has refused the advice of two surgeons, and is now doing well; but the danger of a sympathetically irritated eye is constantly before him. The pathological investigation is then mainly restricted to eyes enucleated before or after sympathetic irritation has developed in the other eye, as results show that under such circumstances full protection to the remaining eye is afforded. Investigation of eyes enucleated when sympathetic ophthalmia of the other eye is present may explain the cause of the trouble in the remaining eye; but there is so much damage done to both that our knowledge only makes us the more desirous to prevent these conditions from arising, and in the multiplicity of conditions the principal cause is lost. When enucleation to forestall sympathetic irritation or ophthalmia is done, or when the operation is performed with sympathetic irritation just beginning or present, the eyeball removed is in a much better state to examine, and more light can be thrown on the cause of sympathetic irritation, since severe inflammatory processes cloud the change from sympathetic irritation to that of sympathetic ophthalmia, and the pathological study is more difficult. My collection contains only one specimen enucleated when sympathetic ophthalmia was present, and in this case there was a double acute glaucoma with sympathetic iritis. At this time I only desire to place before you some specimens of eyes enucleated for the protection of the fellow-eye from sympathetic irritation, or on which it was already beginning or developed, and in these cases good and permanent results have been attained. Four of these cases were due to traumatism; the fifth was of an inflammatory character. All but one of the traumatic cases had the fellow-eye affected, and the

examination of the enucleated eye in the exceptional case justified the operation. In two cases the sound eye became affected shortly after the injury to the enucleated eye. In one case no irritation until forty years had elapsed since the accident to the enucleated eye. In one non-traumatic case there were repeated attacks for a series of years, of irritability in the sound eye, until the pain in the diseased eye and the disturbance of the sound eye compelled operation. In the remaining traumatic case for twenty years the uninjured eye was unaffected, except rendering the myopia more progressive, which rendered an operation imperative for its arrest and to prevent the outbreak of sympathetic ophthalmia later in life. The patients were aged respectively 3 years, 40 years, 47 years, 50 years, and 70 years. Three of the patients were males, and two females. In four cases the left eye was enucleated, in one case the right. In every case the injury or disease involved directly or indirectly the ciliary body; and where the crystalline lens remained in situ or the sclerosed tissue infringing most markedly on the ciliary region, the irritation developed most rapidly in the other eye. Where the crystalline lens was dislocated with weakening of the sclerotic tissue, no irritation appeared for forty years in the other eye. In one case with dislocation of the lens and detachment of the retina and choroid, no irritation had appeared at the end of twenty years in the other eye. In those cases where the iris became entangled in the cicatrix, sympathetic irritation of the other eye developed most rapidly; in one instance, the lens becoming cataractous in the sound eye, while that of the injured one was either absorbed or lost at the time of accident. In short, is it not to injury of the ciliary nerves, with their varied function, and to the damage done to the tissue in which they are imbedded in the different divisions of iris, ciliary body and choroid, that we are to look as the cause of sympathetic irritation in the fellow-eye, and of these the ciliary body and nervous structures in it, with or without involvement of of the iris as the principal part involved? When sympathetic ophthalmia arises in the sound eye, cannot it be traced to inflammatory processes, added to the irritation of the ciliary nerves and involving the iris, ciliary body and choroid? How far the retina and optic nerve participate in sympathetic irritation, it is difficult to say; only we find that in enucleation for sympathetic irritation, the fellow-eye regains the full function of sight.

In sympathetic ophthalmia, however, the involvement of the nerves and retina is a more important factor, and the fellow-eye is not so likely to be restored to full function of sight, as the condition in the enucleated eye and the one affected are more serious on account of marked inflammatory processes.

[Dr. Little then gave in detail the histories of his cases, but all essentials having been already given, it is not important to add them here.]

Stab of Pericardium, Diaphragm and Liver, Exhibited by Dr. Strittmatter.

The specimens were removed from a German laborer, aged 62, a patient in the Surgical Wards of St. Mary's Hospital, under Dr. Mears, who was admitted July 16th, 1882. He had been laboring

for some days under a mental delusion, and after writing a clear, intelligible letter to his wife and family in Germany, stabbed himself with a clasp-knife in the right side of the chest several times, notwithstanding all efforts of the bystanders. He was at once taken to the hospital, and on admission was much excited, with a rather flushed face, but little shock, struggling to escape from the punishment of his supposed crime. Examination showed two wounds: one over and reaching down to the cartilage of the sixth rib of the right side, about one and a half inches from the sternal border, and about two inches in length; the other half an inch from the border of the sternum, and severing from it the cartilages of the seventh and eighth ribs. Closer examination of this wound showed that there were two openings through the costal cartilages about a line apart; the outer passing downward, outward, and backward, the inner, in a direction inwards, downwards, and backwards. Through these openings air occasionally passed when the patient respired violently when struggling, causing a high-pitched sucking and blowing sound. None but slight bleeding took place, and that from the integument. Physical signs everywhere normal except over the lower part of the right lung, where increased resonance was noted, and on heavy percussion a kind of "cracked-pot sound" was elicited. Auscultation revealed diminished breathing sounds over the upper part of the right lung, while respiratory sounds were entirely absent over its lower portion. Heart's action rapid and irregular. Heart sounds feeble, especially the first. Pulse 112, respiration 42 and shallow. There was no sign of internal hemorrhage. Both during inspiration and expiration, when the head and shoulders were raised and he inspired deeply, a peculiar high-pitched blowing sound was occasionally heard, a little to the left and below the ensiform cartilage. It did not resemble the sound produced by gas in the stomach or bowels. Antiseptic dressings were used and morphia given, but he slept little, although nothing was complained of beyond a burning sensation beneath the sternum. The next morning he was calmer, rational, felt pain only during inspiration, and altogether breathed more easily than during the night, although the physical signs remained the same. The abdomen was tympanitic, the pulse full and moderately strong, 92 per minute, respirations 32, and expiration labored, with groaning. Temperature 101.6°. During the next night he grew worse, with restlessness, poor sleep, followed the next morning by cutting pains in the chest at each inspiration, anxious, pinched face, and considerable anxiety as to his condition. Friction sounds were now heard over the whole of the left chest, and on the right side from the apex to the fourth rib. Pericardial friction sounds were also heard. Pulse 100, full and hard; respirations 48, with rapid, jerky inspiration, abruptly terminating, to be followed by a forced, prolonged, groaning expiration. Temperature 103.2°. Evening pulse, 120; respirations, 44; temperature, 103.2°. During the next twenty-four hours all the symptoms, physical as well as rational, of effusion into the pericardium and both pleuras developed; but although the abdomen was tympanitic, no signs of effusion were detected. Pulse in the evening 120, irregular, intermitting; respira-

tions 40; temperature 101.8°. Had a bad night, and next morning seemed much prostrated, with a feeble, occasionally intermitting pulse of 120 per minute; temperature 102.8°; respirations 40, labored and shallow. Low, muttering delirium now set in; he sank rapidly, and died at two p. m., of the 20th, with a temperature of 102.5°. [The surface temperature record, not showing anything of very *decided* interest, is omitted.] Sectio-cadaveris.—Brain; pia mater adherent, thickened in patches and opaque, especially on either side of the vessels, which were filled with dark blood over the upper convex surface of the left hemisphere.

There was a slight amount of serous effusion in the subarachnoid space. The ventricles contained a small amount of serum. Chest.—On raising the sternum the right pleural cavity was seen filled with a thick, fatty looking effusion, with some bands of recent lymph extending from the lung to the chest-wall. The apex of the lung was quite firmly adherent to the chest-wall. The anterior surface of the lung was covered to the depth of $\frac{1}{4}$ of an inch with soft, grayish yellow lymph. A portion of the back part of the inferior lobe was consolidated. The left pleural cavity was only about half-filled, with the same thick layer of lymph and adhesion to the apex that was noted in the right lung. No part of the left lung would sink into water. The pericardial sac was distended with fluid, and both upon its inner surface and upon that of the heart was abundance of lymph connecting the two surfaces by drawn-out bands of the same. There was a large chicken-fat clot in the left ventricle, extending about six inches into the aorta. The right ventricle was filled with blood, with a small clot extending into the pulmonary artery. Examination showed that while there were but two penetrating wounds externally, the knife must have been thrust in repeatedly after partial withdrawal, as there were three openings through the diaphragm, penetrating the liver to the right of its suspensory ligament, and one traversing the lower part of the pericardial sac, and entering the left lobe of the liver for about 1 inch. The other liver wounds were $\frac{1}{4}$, $\frac{1}{2}$, and $\frac{1}{8}$ of an inch deep. There were no traces of peritonitis, although about two ounces of serum was present, probably escaped from the pericardial sac through the wound. The liver wounds did not gape, were ununited and surrounded for about an inch in every direction by a brownish yellow discoloration. The liver weighed 62 ozs.; spleen enlarged and soft; other organs healthy.

Remarks by Dr. Mears.—I was much interested in this case. During life the symptoms of wound of the diaphragm and of the liver were markedly absent, whilst those of injury of pericardium and pleura developed as the interval after the receipt of the wounds increased. The external wounds gave little indication as to the direction taken by the knife after puncturing the thoracic cavity, and as shown by the post-mortem examination, no information as to the extent of injury inflicted. The absence of symptoms of injury of the diaphragm may be explained by the fact that the wounds were in the tendinous portion of that muscle, and being small, did not interfere to any great extent with its function in respiration. In

injuries causing laceration of the muscular fibres attached to the ribs, dyspnoea occurs as a prominent symptom by reason of the impairment of the respiratory duty of the muscle. Moreover, the symptoms may have been masked by those referred to the injury of the pericardium, as in wounds of both of these structures dyspnoea is a prominent symptom. The knife in one of the thrusts passed through both, and involved them in a common injury. The only explanation I can offer of the production of the blowing or rather suction sound which was heard under the ensiform cartilage, is that it was occasioned by the passage of air during respiration through the openings in the diaphragm — the air entering primarily the lung cavity through the external wound. The fact that the air did not pass in and out of this external wound during the act of respiration, afforded good evidence that the lung was not wounded. The wounds of the liver were of such character as to make little or no impression beyond what might occur as the result of injury to the coverings and superficial portions. Puncture of the liver with a trocar is frequently performed with a view of evacuating fluids. Instances are reported in which no fluid has been found, and no harm has been inflicted by the tapping.

Extensive laceration, the result of gunshot wounds or rupture following falls, produce characteristic symptoms of shock and internal hemorrhage.

Secondary Sarcoma of Heart, Lungs and Gall-Bladder, Following Primary Amputation for Deposit in the Femur.

Presented by Dr. Willard.

The specimens exhibited were the heart, lungs, and gall-bladder of a female patient, *et.* 21, whose right thigh had been amputated four months previously for a spindle-celled sarcoma of the lower end of the femur. The apex of the right ventricle was infiltrated with a sarcomatous mass, which extended into a cavity among the columnæ carneæ, forming an irregular-shaped body occupying one-fifth of the space. The walls were softened, and but little of a muscular fibre was to be seen at the apical region. The diseased tissue was very soft and easily detachable, rendering its propulsion into the lungs a matter of exceeding probability at each heart-beat. The walls above the mass were natural in appearance and in thickness; the valves showed no evidence of disease on either side of the heart. The left ventricular and both auricular walls were healthy. The disease had not reached the visceral layer of the pericardium, and there was no abnormal effusion in the cavity of the sac. The septum ventricularum was not involved. That numerous particles had been swept into the lungs, was very evident when these organs were examined. At a large number of points in either lung were to be seen white masses, varying in size from that of a pin's head to that of an English walnut. Some of these were dense, others are undergoing softening, and in nearly every instance the lung substance surrounding was so disintegrated that the mass seemed to be in a cavity containing a drachm or more of sanguinolent fluid. A very moderate degree of pressure would cause a nodule near the surface to burst its pleural covering, and give rise to an accident similar to

the one which was found to have occurred near the right apex. At this point a large sarcomatous mass had excited a degree of inflammation sufficient to fasten the lung to the parietal pleura, and one week before the patient's death, ulcerating through the serous covering, had given rise to an internal hemorrhage that was well-nigh fatal and gave symptoms of sudden collapse, noted in the history. This escaped blood was found in the right pleural cavity, confined by adhesions chiefly to the upper portion of the chest. For the week which elapsed between the hemorrhage and death, it had coagulated, forming chicken-fat clots and other coagula weighing fully two pounds. The pleural cavity below the adhesions contained about two quarts of bloody serum. There was no consolidation of the lungs, save around the diseased foci. The lungs had evidently acted as a complete strainer, and had prevented the passage of emboli; for liver, kidneys, spleen, and all other organs were healthy, save one small spot in the gall-bladder. The brain was not examined. The primary disease in the femur had apparently resulted from traumatism, since no difficulty had existed previously to a severe fall upon the knee. From this time the pain on walking was continuous, and four months later there was decided enlargement of the external condyle and swelling in the popliteal space. The chief points of interest in the case were: First, the traumatism acting as an exciting cause. Second, that the physician who first saw her detected neither fracture nor luxation, nor anything beyond contusion of the joint. Third, the appearance at the end of four months of a pulsating tumor in the popliteal space which presented a decided bruit, but no thrill. This was due to the lifting of the artery from its bed by the sarcomatous mass. Fourth, the non-involvement of the knee-joint, although the nodules had pushed forward the synovial membranes between the condyles posteriorly. The articular cartilage of the femur was intact, although the bone tissue immediately beneath it was extensively diseased. Fifth, the return of the disease, not in the stump but first in the right ventricle, but to failure in circulation and great prostration, which came on from four to six weeks after the amputation, and without anything in the condition of the stump to warrant such depression. The patient seemed in articulo mortis, yet there was no pain and no dyspnoea, only a feeble, rapid heart action accompanied by low delirium and weakness. There were no valve-sounds audible. These symptoms were due, as shown post-mortem, to the deposit and development of the sarcomatous mass in the heart. Nature however gradually accommodated herself to the new growth, and the patient rallied for a time, so as to be able to walk on crutches, eat heartily, and consider herself in good health. She got fatter, and only slight dyspnoea on exertion, with three or four coughs a day, remained to indicate recurrence of the disease. Sixth, a sudden, causeless as to exertion, profuse hemorrhage, from the collapse incident to which she rallied and lived one week, with respirations, 30–38, pulse 130–140. Seventh, the primary and consecutive growths showed a preponderance of spindle cells, while the secondary nodules were composed chiefly of round cells. Eighth, the post-mortem examination throws

great light upon the clinical symptoms, while the great rarity of sarcoma of the heart makes it important to note that there was never any angina pectoris. In Dr. Ingram's report of a case called carcinoma of the heart, in the Transactions of this Society for 1877, the only case ever presented to this Society, angina pectoris was indicated as one of the diagnostic points. In the report of the committee on morbid growths, Dr. Ingram's specimen was shown to be really an alveolar sarcoma. Secondary sarcomatous growths of the heart are mentioned by various authors, but the histories give no clinical signs of the growths. Dr. Barton said that in regard to traumatism causing morbid growths, he considered that they probably had no more causative effect than acting as exciting causes. Dr. Formad asked if the exact nature of the primary growth was known, whether it consisted of round or spindle cells, since it has been stated that the spindle-celled variety never forms metastases. Dr. Seiler reported that the primary growth consisted of both round and spindle cells. Dr. Shakespeare agreed with Dr. Barton as to the origin of the primary growth. He did not consider that injuries were anything more than exciting causes in those predisposed to such

growths. The case presented a typical example of the method of metastasis; we have the growth first developing at the knee, whence particles were carried by the veins to the heart, became there lodged and developed into a tumor, which forms a new centre from which microscopic emboli are carried by the blood-current into the lungs, where they lodge and grow into the nodules seen in the specimen. Metastasis of sarcoma occurs by means of the blood-current, while that of carcinoma takes place through the lymphatics. Dr. Formad could see no other cause for the tumor than the injury of the knee, previous to which the patient had never shown any symptoms of disease of the joint, while shortly after receiving the injury the tumor appeared. The tumor may not necessarily be malignant; there is an inflammation and formation of cells; the malignancy will depend upon the looseness of the cells and the facility with which they can be transported.

Dr. C. K. Mills then read a paper on the Brain in Epilepsy, which did not admit of abstraction.

Dr. Brubaker presented a specimen of tumor of the brain, which, with the accompanying paper, was referred to the Committee on Morbid Growths.

C. B. NANCREDE, *Recorder*.

EDITORIAL DEPARTMENT.

PERISCOPE.

Diphtheria and School Congregation.

The *British Medical Journal* says that a noteworthy instance of the spread of disease by the agency of schools is afforded by Dr. Sykes in his last annual report on the sanitary condition of Portsmouth. During 1881, the borough was visited by a wide-spread epidemic of diphtheria, which caused no fewer than 205 deaths, a mortality from this cause unprecedented in the annals of Portsmouth. Dr. Sykes attributes the wide-spread nature of the epidemic (1) to the carelessness and curiosity of neighbors visiting infected houses, and taking the disease home to their own children; and (2) to the congregation of large bodies of children in schools. This last cause was a most potent factor in the dissemination of infection. In the earlier stages of the epidemic, numerous cases were discovered in which the disease was undoubtedly contracted at two of the Board schools in the borough. This is evident from the fact that, during the first quarter of 1881, two-fifths of the cases either attended these schools, or had members of the same family doing so. Convinced of the importance of closing these places, Dr. Sykes made personal application to the authorities with this object, but unfortunately without success. Later on in the year, it was found that one of these schools was playing a still more important part in the spread of the epidemic, the sudden extension of the disease in its immediate neighborhood being attributed to cases in

which the complaint had been caught at the school. Indeed, during the last quarter of the year, no fewer than seventy-five children had either attended there, or been infected by members of the same family. Another establishment was acting in a like manner, but the authority was now successful in obtaining the closure of the two schools for some weeks after the Christmas holidays (making together an interval of eight or nine weeks), with the effect of causing diphtheria to gradually, but certainly, disappear from the two neighborhoods. A marked diminution in the numbers of those attacked was also observed at the close of the summer holidays.

Vomiting of Pregnancy.

Professor Horwitz, of St. Petersburg, has recently issued a monograph on this subject, which has received a lengthy notice in the *Medical Press and Circular*, from which we take the following remarks on treatment: The legion of drugs recommended is the best proof of their worthlessness—alkalies, alkaline waters, bismuth, laudanum, cerii oxalas, sinapisms, blisters, chloroform or ether spray over epigastrium and back, ice-pills, iodide of potassium, bromide of potassium, nitrate of silver, electricity, etc. Besides this, they can only be employed in the early stages of the affection. Prof. Horwitz recommends absolute rest in the horizontal posture, and in a darkened room, the diet to be nourishing and carefully regulated. Nutrient enemata are counseled under the following regulations: 1. One or two hours before their

employment the colon should be washed out with warm water. 2. Only small quantities should be injected at once (about three ounces at a time). 3. Frequent repetitions of them should be avoided, in order that irritation may not be set up. 4. In case of great prostration, two or three spoonfuls of good wine (Sherry or Port) should be added. 5. In those cases in which enemata are not retained, a few drops of tincture of opium should be added. He considers the "gynæcological" treatment as of great importance. Should there be inflammation, depletion will be useful. Scarification is recommended rather than leeches. Nitrate of silver to the portio vaginalis he does not consider very useful, and on this point he differs from Prof. C. Braun, of Vienna. Mayer's method of repression, by means of laminaria, he recommends. He has twice employed Copeman's method without effect. He looks upon artificial abortion as the only resort in some cases, and speaks of it as follows: In a case of uncontrollable vomiting, in which all means of treatment have been employed in vain, while the disease grows gradually worse and threatens the life of the patient, then the only "chance" of saving her is the interruption of the pregnancy, *i. e.*, artificial abortion must be induced; and, indeed, naturally, in view of the clinical symptoms, and of the height of the danger, the timelier this is done the more rational is the doing of it. Artificial abortion is thus carried out: After preparation of the genital organs by carbolized injections and dilatation of the cervix, he separates the ovum from the uterine walls by means of the uterine sound. He only ruptures the membranes when the process of abortion is delayed. In eight cases in which he has practiced this method he has never seen portions of the placenta retained, while the loss of blood has been but slight, in fact, less than in spontaneous abortion. Transfusion he looks upon as an open question.

Splenic Hypertrophy.

Dr. Lucas reports the following case in the *Medical Times and Gazette*:—

An emaciated and mal-nourished subject, fifty years of age, a Hindoo by caste, and a native of Nassick, came under treatment at Ahmedabad, on account of long-continued ague and diarrhoea, with abdominal enlargement and pain. The abdominal enlargement was of a year's duration. The patient was also troubled with cough, more especially at night. Pulse small and feeble; skin feverish; bowels irregular; appetite poor. The abdomen measured thirty-five inches in circumference at the level of the umbilicus, and ten inches from the umbilicus to the top of the ensiform cartilage, which, in the emaciated condition of the patient, was a great deal. The spleen was enormously enlarged, and the lower end of it could be felt very low down; there was distinct fluctuation in the abdomen, and indeed the appearance of the abdomen left little doubt as to its being distended by fluid. In the front of the thorax, beyond a slight harshness of respiratory murmur at left apex, there seemed nothing abnormal; over both bases there was dulness of the percussion note, especially on the right side, where the lung sounds were inaudible, and vocal resonance was increased; on

the left side these signs were were not so marked. The expectoration was frothy mucus streaked with blood. The lymphatics in the groin, axillæ, and neck, and a few subcutaneous ones over the abdomen, were enlarged. Percussion and palpation of the liver were obscured by the presence of fluid in the abdomen. The consent of the patient having been obtained, the belly was tapped, and ninety-four ounces of fluid removed, and the abdomen supported with strapping. A mixture containing large doses of the muriated tincture of iron and sulphate of cinchonidine in infusion of chiretta was ordered; and the compound camphor liniment as an embrocation for the chest. The diet was liberal, with alcoholic stimulant. He left greatly relieved by this treatment, after a time.

Remarks.—In such a case, where dropsy aggravates distressing symptoms by the fluid pressing on important organs, such as the stomach, liver, lungs, etc., preventing the assimilation of food, causing an increasing serous effusion by pressure on the portal vein, pressure on the bile duct impeding the secretion of bile, and pressure upward against the diaphragm producing pneumonia, etc., we believe it is always a wise plan to operate and remove the fluid, and, if need be, re-tap. No harm could possibly be done with ordinary precautions, and very often, as in this case, considerable relief is afforded, and life prolonged.

Syphilitic Ulceration of the Conjunctivæ in Infants.

Dr. A. W. Calhoun writes as follows to the *Southern Medical Record*:

In the adult we are accustomed to seeing syphilis, in some form or other, take hold of almost any and every part of the body; and even in the infant, it is not unusual that the disease manifests itself secondarily in various ways; but it is so seldom the case that syphilitic ulceration takes place upon the mucous membrane of the eyelid, that I am induced to report the following history:

It is now eight years since Mr. A. J. M. contracted primary syphilis. The disease progressed uninterruptedly till a portion of the upper jaw and a part of the bones of the nose were destroyed, without, however, much disfigurement. Upon the supposition that he had been cured, he married four years ago, and in due course of time a son was born, who was, at birth, and up to the present remains, a specimen of robust health.

One year ago another son was born, who, from birth, has been a typical specimen of hereditary syphilis.* Copper-colored blotches first appeared over the entire body, then eczema upon the scalp, with enlargement of the cervical glands, then ulceration of the right pre-auricular glands. Two months back phlyctenular corneitis began, the phlyctenules running together and breaking down into deep corneal ulcers in each eye, causing the pain and photophobia, and other distressful symptoms so often met with in children with so-called "scrofulous sore eyes."

The eye disease had been in existence two months when the child came under my observation, and in addition to the extensive ulceration of each cornea, the following condition of the lid

*No attempt will be made here to explain why the first child was free from syphilis, and the second had it. The mere fact is given.

appeared: The left upper lid was swollen and angry-looking, and extended downward over and covered the lower lid. Upon everting the lid, a very characteristic syphilitic ulcer was found to occupy the centre of the conjunctiva, being near the size of a three-cent silver coin. It had the ragged and undermined edges, the dirty surface, and other marked appearances, which so readily distinguish the specific ulcer from all other varieties. Aside from the father's history and the general condition of the child, the ulcer itself left no doubt as to the diagnosis.

The little patient was immediately put upon anti-syphilitic treatment. Iodide of potassium was given, in two-grain doses, and gradually pushed to fifteen grains three times daily, with the happiest result. The sulphide of calcium was also given, in one-sixth grain doses, mixed with a little sugar of milk, for its alterative effect. As local applications, the sulph. atropia (gr. j to $\frac{3}{4}$ j) was used upon the eyes, for its curative influence upon the corneal ulcers, and an ointment of the yellow oxide of mercury (gr. $\frac{1}{2}$ to $\frac{3}{4}$ j) applied to the edges of the lids, which had become excoriated by the profuse lachrymation. The eyes were kept as free from matter as practicable, but throughout the treatment no application was made to the conjunctival ulcer. The child has now been under treatment one month, and the syphilitic ulceration of the lid and every external symptom of the disease has disappeared, though the phlyctenular inflammation of the cornea still remains to a slight degree.

The history of this case is recorded, not because of the rapid recovery under this particular treatment, but because of its infrequent occurrence. In so far the case is of special interest. I have met with a few similar cases among adult hospital patients, but neither in a very large hospital experience, nor in a private practice of a good number of years, and comprising many thousands of patients, have I ever before seen the disease upon the mucous membrane of the eyelid, in the infant.

Strangulation of the Bowel.

Dr. J. Fielden Howard reports the following case in the *British Medical Journal*:

Mrs. C., aged 56, had during the forenoon two evacuations from the bowels, and afterwards went out to take tea with friends. The next day she recognized distension of the belly. Upon the following day (the second) when I saw her, she was moving about and complaining of distension and colicky pains. The next day (the third) I was called to see her; she had now great pain and vomiting. Upon examination, I was enabled at once to diagnose obstruction of the bowels. At the first, the distension seemed to be confined to the smaller bowels; but afterwards the larger were enormously distended, and their vermicular action most marked and frequent. Three or four weeks before death, the sigmoid flexure was greatly distended, and sharply defined by its immobility. There was no evidence from physical examination, either external or by rectum or vagina, the uterus being very movable, of the seat or nature of the obstruction. There was an account of antecedent uneasiness in the rectum, mani-

fested by diarrhoea (so-called), and accompanied by a feeling of inefficient evacuation; but not of any bloody or mucous discharge, and the feces were described as being lumpy and not small in calibre. During the whole course of the disease, the pulse varied both in force and frequency. The temperature was first normal, and then below normal; and the urine was excreted in proper quantity.

The treatment consisted of the total exclusion of solid food, which was very carefully followed out; unirritating injections; and the hypodermic injection of morphia, night and morning. This drug admirably controlled the vomiting and pain.

At the *post mortem* examination, the bowels were very much congested. A little lymph had very recently been poured out. The bowels were quite free as far as the upper part of the rectum, where it becomes bound down to the wall of the pelvis. Here the bowel seemed suddenly to terminate. Upon removing and opening the gut, there was an annular ring of ulcerated scirrhus, so tight that it supported the weight of three gills of water without leakage.

The interest of the case centres in the fact of disease of this grave character having progressed to complete obstruction without professional aid having been obtained; the apparent suddenness of the attack; the very little light thrown upon the nature of the case by the previous history; and the complete negative evidence of most frequent examinations of the rectum, both by myself and other medical men. I may add, that she was a woman of remarkable placidity of temperament. One sister had died of cancer of an ovary; another of cancer of the breast. She declined all operative procedure.

Electrolysis in Partial Trichiasis.

Some method of getting rid of individual cilia, without displacement of those in their immediate neighborhood, has long been a desideratum. We often see several hairs growing in a wrong direction on the lid border, the remaining cilia being in a perfectly normal position.

Ophthalmic surgeons have had recourse to one of the following methods for the relief of the above condition: Epilation, which is, however, unsatisfactory, as the irritation of the young hairs will most certainly increase the irritation, which the epilation for a time relieved; the second, or classical method, is snaring of the hair and turning its direction of growth outwards instead of inwards; but the snared hairs are very liable, sooner or later, to resume their previous vicious direction.

Mr. Arthur Benson, *British Medical Journal*, December 16, 1882, finding these operations unsatisfactory, has adopted the following plan: "To the negative electrode I attach a rather fine gold electrolysis needle, and insert the point of this to a depth of about four or five millimetres along the hair to be destroyed, so that its point should reach well above the root. I then applied the positive electrode to the lid near the outer canthus; contact was conveniently made by wrapping some wet cotton wool round the end of the wire. In a few seconds, the tissues immediately around the needle (negative electrode) began to show white, and soon a distinct bubbling of hydro-

gen gas could be observed. Half a minute or so, according to the strength of the battery, usually sufficed to completely loosen the hair; I then withdrew the needle, and the positive electrode, and with the fingers or forceps removed the hair. It should come away without requiring the slightest drag, and bring with it a gelatinous-looking mass of dead tissue. If the hair be not sufficiently loose, the needle must be reapplied for a few seconds. The amount of inflammation of the lid resulting is usually not great."

In 120 cases so treated no untoward result was seen.

The advantages which the doctor claims for his method, over epilation, snaring, or the actual or potential cauteries, are these.

1. Any individual hair can be destroyed without injuring those beside it.

2. The hair can be got rid of at once and forever.

3. Hairs of any length, strength, or position, can be treated.

4. By its early use, it will render unnecessary many of the more formidable operations on the lids, besides saving the patient much misery.

If applicable for the ciliae, electrolysis should be equally applicable for the destruction of hair-follicles elsewhere, in moles, or hairy-faced females.

A Cure for Intractable Chronic Cystitis, and Confirmed Prostatic Retention of Urine.

In *The British Medical Journal*, Dec. 9, 1882, Sir Henry Thompson says: "I have long been anxious to discover a means of affording some permanent relief to those who suffer with severe and long standing prostatic diseases. I refer to a condition in which the patient, having for several years relied entirely on the use of a catheter for the removal of all his urine, finds the bladder becoming so intolerant of its contents, that the act of catheterism, at first perhaps employed but three or four times in twenty-four hours, must now be repeated, under penalty of unendurable torture, at least every hour or hour and a half. His time is indeed chiefly spent, both by day and night, partly in suffering from retained urine, and partly from painful catheterism for the sake of the temporary relief which it affords."

It is in these cases that he recommends the suspension of all action on the part of the bladder for a few days only, and to prevent any accumulation of urine within the organ, and thus allay the constant and painful want to pass urine. Abolish catheterism altogether, with its irritating effect upon the urethra: we might then hope that the inflammation of the bladder will subside and its tolerance of urine considerably increase.

In order to do this, he has recourse to the following proceeding: "First, placing the patient in the lithotomy position, under ether, I pass a grooved median staff into the bladder, and make, from the raphe of the perineum, a small vertical incision just above the anus, large enough only to admit the index finger—the incision to terminate in the staff at the membranous portion of the urethra, which should be divided for half an inch at most, so as to admit the finger to traverse the canal to the neck of the bladder. Then, having withdrawn the staff, I insert a large vulcanized catheter or tube, say about No. 20 (English scale),

with its extremity just within the bladder, fastening it there by a tape to a bandage round the waist; the tube to be retained as a channel for the urine, for several days at least." Sir Henry has now performed this operation in ten cases, and with very gratifying results; he attributes the benefit to a temporary suspension of function in both the bladder and the urethra; in the bladder as a containing viscus, in the urethra as a channel or transmitting one. By means of the tube the urine leaves the body almost direct from the ureters, while the bladder and the urethra, being in a state of perfect quiescence, cease almost immediately to be inflamed; all muco-pus disappears, and the urine is discharged in as healthy condition as it leaves the kidneys. He removes the catheter on the 10th to 12th day, and allows the wound to heal.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—The Marine Hospital Service has published a "Preliminary Report on the Yellow Fever Epidemic of 1882 in the State of Texas." It is a pamphlet of sixty-three pages, containing a record of the correspondence, telegrams, etc., in connection with the subject.

REVIEW OF RECENT WORKS ON OTOLOGY.

The progress of Otolology is upwards and onwards; for in all the medical centres, such as Vienna, Berlin, London, Philadelphia, Boston, and New York, the hospital patients with diseases of the ear are attended to by an aural surgeon, who is a member of the staff, and should be also a member of the medical school committee for the examination of students who are about to graduate. The profession (as well observed by an able London hospital surgeon) is on the eve of a new departure; for it is a growingly recognized fact, that such serious diseases as *pyæmia*, *abscess in the brain*, some obscure forms of so-called *rheumatic fever*, attended with *ulcerative endocarditis*, and many others—for the most part rapidly fatal disorders—have their starting-point in the ear.

Another Irish surgeon: states "Morbid conditions of the ear are closely allied with a variety of morbid states of other important organs, more frequently and especially the brain and nervous system. A correct understanding of these states must be in a sense dependent upon an accurate knowledge of aural therapeutical and pathological facts. Our powers of diagnosis in nervous and mental affections are largely increased and influenced by the correct appreciation of the etiology of the every-day occurring troubles in the ear.

Dr. T. Lauder Brunton of London, the well known able lecturer on materia medica and therapeutics of St. Bartholomew's Hospital, thus writes: "The serious results of neglected ear disease are now so generally recognized, that no one can feel himself thoroughly qualified to practice his profession without a knowledge of aural surgery."

The numerous published works on the ear and its diseases are an evidence that there is a demand for them by the regular members of the profession. We have now upon our table the following, published in 1881-82:

1. "Imperfect Hearing and the Hygiene of the Ear," L. Turnbull, M. D., third edition, Philadelphia, 1881 (as expressed by D. A. Hartman, of Berlin).

The author of this work has done much for the spread of otology in the United States.

2. "A Treatise on Aural Surgery," by H. M. Jones, M. D., Cork. Second edition, London, 1881.

This work has kept up the reputation of the Irish school of otology, and Dr. Jones is a worthy successor of the celebrated Sir Wm. Wilde, of Dublin.

3. "Die Krankheiten des Ohres und deren Behandlung," by Dr. Arthur Hartman, Kassel, 1881.

This is a valuable hand-book for beginners in otology, as well as for the use of the general practitioner.

4. "Lehrbuch der Ohrenheilkunde mit Einschluss der Anatomie des Ohres," von Dr. A. V. Trölsch. Seventh edition.

The advent of this seventh edition of the work of the oldest and one of the most distinguished professors of the University of Würzburg, shows the importance attached to the study of this class of diseases in Germany; and no one has done so much to define the position of otology in the science of medicine. This work, published at Leipzig in 1881, comprises 664 pages, corresponding to the ever-increasing development of otology.

5. Another work by this author has been recently translated by Dr. Green, of Boston, from the German ("Diseases of the Ear in Children," originally published as a part of "Gerhardt's Handbuch der Kinderkrankheiten"), published in New York, 1881, Wm. Wood & Co.

6. "Diseases of the Ear," by George P. Field. Third edition, London, 1882, enlarged, with colored plates.

A hand-book of a practical character.

7. "Lehrbuch der Ohrenheilkunde für Practische Ärzte und Studierende," von Dr. Adam Politzer, K. K. A. O., Professor der Ohrenheilkunde in der Wiener Universität Stuttgart. Verlag von Ferdinand Enke, 1878.

Politzer's text-book on the "Diseases of the Ear and Adjacent Organs," for students and practitioners. Translated at the request of Professor Politzer and edited by James Patterson Cassell, M. D., M. R. C. S., aural surgeon and lecturer on "Aural Surgery" at the Glasgow University. With 257 original illustrations, two volumes in one, 800 pages. Bailliere, Tindall and Cox, London; Philadelphia, H. C. Lea & Co., 1883.

Dr. Adam Politzer, a distinguished aural surgeon of Vienna, has done much for this department by his numerous scientific investigations of the physiology and pathology of the human ear. From 1862, in which year he published his first investigations and experiments with "Lucæ" or the origin of a certain crackly sound in the ear, and determined that it was not in the tendon of the tensor tympani but in the eustachian tube, up to the present day, when he has issued his completed work, his labors have been most important, and the value of his work is best seen by the numerous extracts from his writings by every otologist who has written on the diseases of the ear. As evidence of the above, in a work on this subject published in New York in 1873, it has fifty quotations from his writings.

It is no wonder then that this work, in two volumes—the first issued in 1878, and the second in 1881—was looked for with much interest by the profession; and much satisfaction is felt that so able an aural surgeon as Dr. Cassell was willing to undertake the labor of translation, with his extensive practice. The work has been accomplished both to credit of the author in providing such a valuable text-book, and to the translator too much praise cannot be given for the manner in which he has performed his part and given us a work in flowing, readable English, and most careful wording of the authors methods and treatment, by one who has worked in the laboratory with his distinguished teacher.

A full review of this work would occupy too much space, and nothing less would do it justice; and we would simply state in conclusion that it is unnecessary to say anything more in regard to the reliability and efficiency of the author. He is an authority wherever the science of otology is known. Every physician should have this most valuable and interesting work.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, - - -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

SHALL PHYSICIANS LEARN ANATOMY OR NOT?

For ages, in most countries, the position of the physician so far as regards his anatomical studies, may be said to have been between the devil and the deep sea.

On the one hand, the demands of the public and the law of the land hold him responsible for an intimate knowledge of the human body and its workings; on the other hand, all sorts of obstacles are thrown in the way of his acquiring that knowledge. Vivisection is discountenanced, and his supply of anatomical material is either wholly cut off, or so limited that he cannot by any legal means provide sufficient for his own instruction.

We pronounce openly and boldly against this injustice. We denounce as absurd and discreditable to civilization the superstition which refuses a free supply of anatomical subjects for dissecting purposes. We brand as infamous the laws which on the one side subject surgeons to heavy damages for malpractice, and on the other withhold from students of surgery the only means by which they can acquire their knowledge.

Such laws can only have one of two results—to produce ignorant charlatans, or to lead to the obtaining of subjects for anatomical study by irregular means.

Which is the worse of the two? From which would the community suffer the most?

Undoubtedly, from the former.

Superstitious veneration of corpses is absurd and degrading. Bentham was bold and enlightened enough to leave his by will to be dissected. What nobler use could it be put to? To be eaten by worms? To decay in a close coffin?

There is a sentiment about sepulture which is commendable. The right of property in a corpse, and the prevention of trespass on a burial lot, are points that should be recognized. But far wider latitude should be allowed in the obtaining and the shipping of bodies for anatomical purposes.

Under safeguards which could be easily arranged, the supply of subjects could readily be increased tenfold, and that would more than fill all the demand.

All violation of graves could be avoided by a

more liberal recognition of the purchase, sale, and transportation of bodies. The only reason why this liberality of action is not conceded, arises from superstition and prejudice. It is a survival of the time when men mummied and worshiped the dead bodies of their kings and ancestors. It is unchristian, it is unenlightened.

Christianity condemns and rejects this worship of the dead body. To the Christian the body is noble only as it is the house of the soul. The soul once gone, the corpse is as nothing; it is the *exuviae*, the cast-off or worthless garment, of no honor, of no worth.

In view of circumstances which have recently happened in this city, in Richmond, in Montreal, and other American cities, we appeal to the profession and the community to maintain the ground of science, philanthropy, and Christianity, and not to be cowed by the clamor of the ignorant.

Graves have been opened, and bodies secretly carried off to the dissecting-room—so it is said. Be it so. The majesty of the law has been violated, the feelings of relatives wounded.

Grant all this. We deliberately reply that if by the increased knowledge thus obtained one single important life has been or will be saved, if one poor, suffering human being has been or will be spared the agonies of disease and released from the rack of pain to return to useful life, it is worth the digging up of a whole graveyard of corpses.

The law is majestic when it is enlightened, and when it favors knowledge and beneficent studies; not when it opposes them. Sentiments are contemptible when they stand in the way of relieving pain, or make one blind to its presence. "Madam," said Dr. Johnson to a lady once, who was entertaining him with her sentimental sorrows, "Madam, are you aware that it is estimated that there are on the average seven persons in London who are dying of starvation?"

The position that the profession has taken in this matter has not been brave, and that which the institutions interested have assumed has been little better than cowardly, if we are to take as true what the newspaper interviewers report of their talk with trustees and professors.

It is the duty of the profession to beat down this superstition about dead bodies, to discourage all foolish sentimentality, to uphold the importance and propriety of post-mortems, and to insist on the necessity of an abundance of anatomical material. A medical college which takes a student and does not furnish him an ample supply of dissecting material, is a fraudulent institution, and will prove an injury and a discredit to the whole chapter of colleges, and to the profession at large. To try to shift the responsibility on any one man is cowardly and contemptible. For the others to plead ignorance convicts them either of falsehood or neglect of duty.

We say, let the profession and the colleges insist on their right to the material indispensable to professional instruction, and insist upon laws that will concede it.

FILTH DISEASES.

It seems strange that it should be so difficult to impress the average man with the great influence that filth has in producing disease.

Every one who knows anything about sanitary science, realizes, or at least says he does, that cleanliness is truly next to godliness, that purity both of body and of surroundings is very conducive to health, while the opposite condition is productive of disease, of the most serious and fatal diseases with which poor human nature is afflicted.

Yet, while admitting this well-established fact, those who ought to know and do better, fail to put its significant teachings into practice.

Why this is so, we candidly confess we are unable to divine.

Why the thoroughfares of our large cities are allowed to remain so filthy, and why the average citizen is so sparing of soap and water and of general cleanliness in all his surroundings, is perfectly inconceivable.

It may be that those who devote themselves in an especial manner to matters of sanitation, view the question from a prejudiced standpoint, and feel that all should have the same feelings that they have.

But this (even granting that such a criticism is made) is not a reasonable one.

The value of cleanliness and the dangers of filth have been so repeatedly, so forcibly, and so practically placed before the public, that they cannot, in justice, argue ignorance of its value, or claim that they do not realize the danger of neglect, unless they admit that they are unthinking and unreasoning beings.

The expense of cleaning a city is no valid excuse. In Philadelphia we have now expended some \$10,000,000 for the partial and uncompleted erection of buildings for the use of the officers of the city, whose duties could have been performed just as well, and probably better, in buildings costing only one-twentieth as much; yet when a competent party offers to take the contract for cleaning the city for five years at \$500,000 per year, expending some \$200,000 for new and approved machinery, but little interest is manifested in his offer.

The relative value of the two expenditures to the public and to the material wealth of the city cannot be compared; the one is so infinitely greater than the other, that they do not admit of comparison.

A few days ago, before a meeting of a committee of Councils, Dr. John M. Keating said that in his travels in China and India, he had noticed that the most offensive form of house drainage was exposed to the air, and was in Bombay collected every day and removed into the ocean. In these countries he had found that such diseases as diphtheria and typhoid fever were practically unknown.

Do let us sink our apathy in this all-important matter of personal and public health; let us cast aside our national and ridiculous egotism; let us remember that as a nation we are very young, inexperienced, and immature, great though we may be in natural resources; and so realizing, let us take example from older and more intelligent countries, where, having instructed the masses in hygiene, sanitarians have been able to demonstrate by facts—solid, indisputable facts—the powerful influence of hygiene and pre-eminently of cleanli-

ness, in not only reducing the death-rate, but in actually increasing the personal and general wealth of the inhabitants and of the nation.

QUARANTINE AGAINST SYPHILIS.

Of all the contagious diseases, syphilis undoubtedly heads the list.

We have quarantine regulations against small-pox, yellow fever, and the like; but syphilis is left to regulate itself.

That this is wrong, every man who stops for a minute to reflect, will perceive.

We should have a system by which immigrants who exhibit decided evidences of what is by far the most serious and fatal disease known to our profession, might be secluded until the evidently active poisonous condition of their systems has been modified.

We realize the indefiniteness of our knowledge concerning syphilis; but we do know that it is an eminently contagious disease, as much so as any other, and that its source of contagion is not limited to impure sexual intercourse, but may be due to any contact of any abraded or absorptive surfaces.

So realizing, we must confess that this dread and terrible disease calls imperatively for the strictest quarantine regulations.

OUR DRINKING WATER.

At the present time we have a great deal of sickness in our city, and at the present time our Schuylkill water is an abomination to every sense—of smell, taste, and sight.

The Chief Engineer of the Water Department is having a wrangle with Councils, and the people are suffering. It is all very nice to talk about the influence of oxygen in purifying water, and to make the statement that water purifies itself; but we cannot help but believe that water that receives human refuse and mill waste and then flows for even three miles without further contamination, must be unfit for drinking purposes.

While it will be very difficult to work a radical change in our water supply, each individual has it in his power to do away with the injurious

effects of drinking impure water by a very simple and inexpensive device.

First *boil* and then *filter* all your drinking water, and you can laugh at disease from impure water.

SMALL-POX IN BALTIMORE.

We sounded the warning some time since that small-pox was approaching from the southwest; it has now reached Baltimore, in which city it is raging so severely as to seriously interfere with business. The people blame the health authorities for not having taken proper precautions, while in truth the people themselves are to blame for neglecting the only precaution of great practical value against small-pox, namely, vaccination. The city has appointed eighty additional health physicians, and the School Board twenty more. A law making vaccination compulsory has been passed. On New Year's Day over 300 prisoners were discharged from the city jail lest they might catch the disease. All this is very good, but it seems like locking the stable-door after the horse is gone. Let us take warning—advise all your patients and all your friends to be vaccinated at once, no matter how recently it may have been successfully performed. With pure material it is a trifling and harmless operation, and may be the means of averting a world of misery.

NOTES AND COMMENTS.

Gouty Tumor of Penis.

At a recent meeting of the Glasgow Medico-Chirurgical Society (*Glasgow Medical Journal*), Dr. H. C. Cameron related a case in which there was a hard little tumor situated between the dorsal and right lateral aspects of the penis, about an inch from the pubes. It caused no pain except during erection, when there was always severe pain in the part, and the penis became distorted and bent at a sharp angle. He had seen one other similar case.

Iodoform.

The *Medical Times and Gazette* says that Dr. Langsteiner reports a case of iodoform poisoning. The patient, an octogenarian, was operated on for submaxillary cancer, and about one drachm of iodoform was used as an antiseptic dressing.

Death ensued in six days, the prominent symptoms being cerebral.

Dr. Benzan reports favorable results in six cases of diphtheria treated by local applications of finely powdered iodoform by means of a small camel's-hair brush.

Function of the Bile.

Generally the opinion has been adopted, that the bile possesses an anti-fermentative action. Dr. F. Röhmman (Breslauer ärzsl. Zeitsch, 1882, No. 7) has specially investigated this subject. He had two dogs with a fistula of the gall-bladder; to both he gave for their food nothing besides meat, and he found the feces grayish-white, dry, easily broken-up, and consisting mainly of inorganic substances. In the urine of neither could be noted any increase of ethereal sulphuric acids, a fact which undoubtedly could have been observed in the intestinal canal in case putrefaction had been augmented. A third dog with a fistula of the same kind continued in a normal condition when fed for a long time with toasted white bread; but as soon as he was put on an exclusive meat-diet, diarrhœa set in, which happened also when fat was added to his food. The fat under such circumstances is not absorbed, but is found again in the feces, and mainly in the form of soap and free fatty acids.

Electricity as a Cardiac Stimulant.

Professor Von Ziemmsen has given us some valuable information on this subject. According to his researches, the induced current has no influence whatever on the force or frequency of the cardiac contractions, while the continuous or battery current distinctly affects them.

The Importance to be Attached to Karyokinesis.

In a similar manner as Killiker and Altmann, so also Dr. N. Uskoff (*Arch. f. Mikrosk. Anat.*, xxi., p. 291) has made use of the presence of Karyokinetic figures in embryones to form deductions concerning the greater or smaller share the parts had on the general growth of the objects examined. Wherever there are no cells found with karyokinetic appearances, the tissue does not proliferate; and in case growth takes place notwithstanding, it can, according to U's view, only do so by increase of the volume of the single cells or by minute accretion to the intercellular substance, or lastly cells developed somewhere else, immigrated to the tissue. The younger the embryo, the more rapid that phases of karyokinesis runs its course, which is characterized by the rod-and-barrel-shaped figure.

To judge from the investigations made so far, karyokinesis evidently plays an important role in the earliest growth of the component parts of an embryo, *i. e.*, while not influencing the type or the form of the tissue, which has to be traced to the nerve-cells, it evidently is necessary for the normal growth and further development of each tissue. The figures do not change with the nature of tissue involved but, seem to depend upon the earlier or later stage of development.

Chemistry of Acute Yellow Atrophy.

That we have known always so little of the chemical change taking place in the organs mainly affected in acute yellow atrophy of the liver, is due, we think, to the fact that the disease is really a rare one, and mostly observed in pregnant women only, and occasionally after nervous shocks or in syphilis. Prof. Lewin had recently in his clinic a case of this fatal malady, and Dr. E. Salkowski has taken the trouble to make a chemical examination of the liver, spleen and kidneys, to find out their percentage of pepton and hemi-albuminose (*Centralbl. f. d. Med. Wissensch.* 1882, 41). The percentage in these organs, twenty-four hours after death, was as follows.

	Pepton.	Hemi-albuminose.
Liver	2.51.	0.36.
Spleen	2.39.	0.48.
Kidneys	1.80.	0.20.

A few more similar investigations, and we shall soon know more of the actual pathology of this still rather obscure disease than we can boast of so far. The malady is usually so rapidly fatal that it is difficult to arrive at correct conclusions. For the details of the analysis, we refer to the original: *Virchow's Arch.* lxxxviii. p. 394.

Cirrhosis of the Liver.

If cirrhosis of the liver were solely due to great increase of areolar tissue starting from the branches of the portal vein or the interacinose capillaries, the central hepatic vein would have to be found invariably in the middle of the little islands of liver-cells. This, however, is usually not the case; on the contrary, the branches of the hepatic vein are generally met with in the middle of the new-formed areolar masses. While examining several recent cases of beginning cirrhosis, Dr. Ch. Sabourin (*Du rôle, que joue le système sus hépatique dans la topographie du cirrhose du foie. Revue de Med.*, 1882, p. 465) found that the development of areolar tissue started as much or even more from the neighborhood of the hepatic veins than from that of the portal branches;

both systems of rapid morbid increase of intercellular tissue anastomose in manifold ways, and divide in this manner the liver-acini in fragments; these fragments of the hepatic acini form the "hob-nails" of cirrhosis, and we know now the cause why they do not contain a central vein.

We have, therefore, to assume that in cirrhosis of the liver in a large number of cases the morbid new growth of areolar tissue does not start alone from the neighborhood of the portal branches—inter-acinose—but also from that of the branches of the hepatic vein, therefore—intra-acinose (*Cirrhose Cireineusse*).

Acute Pneumonia an Infectious Disease.

We have during the last six months frequently taken occasion in the *Medical and Surgical Reporter* to mention every kind of evidence going to prove that acute lobar pneumonia is an infectious disease, which should be classed amongst the infectious fevers. To-day we again have the opportunity of doing so. A not less careful investigator than C. Friedländer (*Virchow's Arch.* lxxxvii. p. 319) examined the lungs of eight cases of fibrinous pneumonia, and found in all of them micrococci, having nearly the same size and shape in every case alike. They had a somewhat ellipsoid form, and were met with mainly in the fibrinous props of the bronchi and the alveoles; and also in the lymphatic paths.

Ligation of Common Carotid Artery.

A patient, age 30, was admitted into hospital with scarlet fever. The case progressed towards convalescence in the usual way, until on one day the patient complained of sore throat. The throat, particularly on the left side, became much swollen, accompanied by a feeling of suffocation. Soon after, the patient brought up a considerable quantity of blood, when the swelling and difficulty of breathing subsided. The alternate enlargement of the neck, hemorrhage and subsidence of the swelling, were repeated several times, until the patient's condition became critical, he having lost forty ounces of blood in all, and there was no sign of arrest of hemorrhage. There was considerable bulging of left side of pharynx, dyspnoea, and aphonia. Mr. A. J. Pepper (who reports the case in *The Medical Press and Circular*) tied the left common carotid artery at the upper border of the omo-hyoid muscle; carbolized catgut was used, and the operation performed antiseptically. For a time, respiration threatened to fail; but he rallied in three or four hours, and made an uninterrupted recovery.

Treatment of Fracture of the Patella.

In five cases Dr. J. English has found the following procedure most successful for the cure of fracture of the patella. He forms a Petit's boot by applying bandages of plaster of Paris and oakum, so that boot and extremity form one solid whole. The broken parts are approximated by a double-headed gutta-percha or flannel roller, so that both heads cross as well above as below in the bend of the knee. The fragments did not heal alone much sooner, but also more perfectly than he had ever seen by any other method. It is by all means rather remarkable, that nobody before should have made use of such an immovable bandage as that of gypsum for fracture of the patella, and English's procedure surely merits a thorough trial by our surgeons also. (*Wien. Med. Blätter*, No. 14.)

To Disguise the Odor of Iodoform.

We have had many queries as to how this may be best accomplished; we therefore give every reliable report on the subject. The following is from the *New York Medical Journal and Obstetrical Review*: "Having tried nearly all the devices that have been suggested for mitigating or disguising the odor of iodoform, and found them all of little or no avail, we have lately come nearer to the object by using oil of eucalyptus according to the following formula:

R. Pulv. iodoform.	3 ss
Eucalypt.,	3 ss
Vaselin,	3 iv.
M. ft. ungent.	

This ointment is not without odor, but the odor is not that of iodoform."

Local Therapeutics of Liver Diseases.

According to the experience of Dr. F. Mosler and his pupils (*Deutsche Med. Wochenschrift*, 1882, No. 16), the introduction of water into the bowel (by funnel and tube) caused a decided alteration in the secretion of the liver, by augmenting the percentage of water in the bile and reducing that of the solid constituents. Medicamental additions to the water, especially of salicylic acid and its salts as well as of iodide of potash, are excreted partially again by the bile. This manner of influencing the function of the liver, locally, does not recommend itself alone for icterus catarrhalis, for which it has mainly been made use of for some time already, but also in other diseases of the liver, as for instance in interstitial and suppurative hepatitis, and perhaps also in gall-stones, where, if early and frequently administered, these water injections, with or without the addition of appro-

priate remedies, may be able perhaps by augmenting the percentage of water in the bile and reducing that of its solid component parts, to dissolve them, or to keep the bile at least in such fluid state that the reformation of the stones would be prevented, and at last such a change produced in the chemical composition of the bile, that we might speak of a radical cure of gall-stones.

CORRESPONDENCE.**Bovine vs. Humanized Virus.**

ED. MED. AND SURG. REPORTER:—

In the *Reporter* of Dec. 25, I notice in an article under the caption of "Bovine vs. Humanized Virus" the surprising (to me) statement that "Since the old mode of vaccination with the human crust has been supplanted by the bovine lymph, the difficulty of producing vaccinia has increased ten-fold!!" Now I think the new way a decided improvement over the old, and I cannot conceive how any one can fail habitually in primary cases, if a moderate degree only of care is exercised. In Jan. and Feb. of the present year, I vaccinated one hundred and ninety-three "primary" without a single failure. The material used was partly powdered crusts and partly the contents of lymph tubes procured from J. L. and L. F. Suesserott—the only implement a "vaccinating comb" with which the scarifications were made. I always scarified until about a drop of blood collected on the region to be operated on, then if crust was used, a minute portion was mixed with the blood and well rubbed into the wound with the reverse end of the comb.

I also had a number of cases like the following, (and who has not?) They had been vaccinated when children, since which time repeated and recent attempts had been made, but it would not "take." In this class of cases so far as heard from I did not have a single failure. I think the most usual cause of failure is in not scarifying deep enough, and too close attention to directions on packages of vaccine material, viz: "If a drop of blood flows, wait and wipe it off." In none of the cases coming under my observation was there any sloughing, erysipelas, convulsions, or a single case of "scrofula," or eczema. I think this old custom, like many others, is like old china, valuable only because of its age, but is unsuited to present use.

J. W. McCausland, M. D.

Bryan, Ohio, Dec. 26th, 1882.

Digital Assistance in Labor.

ED. MED. AND SURG. REPORTER:—

I beg to add my testimony of the value of digital assistance during the first stage of labor, as described by Dr. Gillette in *Gynecological Society Transactions*, and noticed by you in No. 19, page 520.

It was almost a secret among many of the older obstetricians practising in the country districts of England, and many a lady would say, "I prefer

Dr. A., he helps me so much, whereas Dr. B. sits and does nothing."

During the past thirty years I have attended over four thousand cases, and I know that it has shortened the labor and saved me the trouble of using the forceps in a majority of cases, and it will bring on uterine contractions when ergot will not. With a rigid, slow dilating os, the extract of belladonna, smeared on the fingers, will work like a charm.

The same can be said of the perineum. I have often succeeded by digital manipulation, and plenty of adeps, in dilating, when I know otherwise I should have had a ruptured perineum. I have yet to record the case where I have had to use sutures; little rents will occur, but with the above treatment very seldom.

JOHN UNDERHILL, M. D.

Hamilton, Ohio, Nov. 23d, 1882.

Turpeth Mineral and Calomel in Laryngitis—Iodide of Potassium.

ED. MED. AND SURG. REPORTER:—

There are many things worthy of remembrance which daily occur to us as practitioners, which we do not communicate to the journals because we suppose they may not be sufficiently new or remarkable; but which nevertheless may be instructive to many readers.

In your issue of Nov. 11th, I notice two articles in regard to the use of two important remedies, in both of which I have had corroborative experience. One relates to the use of Turpeth mineral in laryngitis. I have used this medicine in croup for near forty years, and consider it one of the most reliable remedies in that disease. It is the most prompt emetic I know of, and has the effect of producing a speedy and large secretion and expectoration of mucus, which often at once arrests the disease. If given early in attack, it is often all that is needed. If given later, it is often successful. But it is not to be relied on alone in cases where the disease is confirmed. In this case emetics can only occasionally be given—once in 3 or 4 or 5 hours. The strength must be husbanded, nutriment must be carefully administered and allowed to continue on the stomach. And now a slower process of relieving the congested lining of the larynx and trachea and separating the plastic exudation must be relied on. Above all the means which I have seen used, calomel is the most reliable—given with a minute portion of ipecac in doses of from a half to one grain every hour or so. A very little soda bicarb. may also be added to the powders. In addition to the above, the patient should constantly inhale warm vapor. The steam generator should be in constant operation at the side of the bed, and the head so hooded as to keep the vapor over the nose and mouth. With these means, Turpeth mineral, calomel and steam, and keeping up the patient's strength by nutriment and sometimes stimulants, I have saved a number who I think would otherwise have perished. Some have recovered after a week of anxious care. Of course the effect of the remedy on the mouth, bowels, etc., needs watching.

It has been known to many for a long time that some patients cannot take iodide of potassium. This is stated in the old editions of the "United

States Dispensatory," and in Stillé; not so fully in the recent work of Wood. I had prescribed it for many years without noticing any unpleasant effects, when one day I ordered $\mathfrak{z}\text{j}$. of the salt to be added to $\mathfrak{z}\text{iv}$. of infusion of gum guaiac, to be taken in divided doses, by a rather nervous man who had a recent attack of lumbago. A few hours after I was sent for in great haste, and found my patient running about the house in great distress, his eyes weeping and red, with his hand to his throat, unable to speak but in a whisper, and saying that he felt as if he would choke to death. At the same time his nose was stopped, and he felt a distress as if he had been poisoned. He had not taken more than 8 or 10 grs. of the medicine, but thought that he felt worse at every dose. I gave him some morphine, applied a warm pack to his neck, and had him inhale warm vapor.

Finding my patient's symptoms to correspond so nearly with those noticed in the works I have referred to, I thought it very fair to attribute them to the iodide of potassium, and I would be much afraid to give the same person the medicine again. Since then I have met with asthmatic and bronchial cases where the same idiosyncrasy was manifested. It is therefore wisest to begin the administration of this most valuable remedy somewhat tentatively. A. W. ROGERS, M. D.

Paterson, N. J.

A Case of Cataract with Complications.

ED. MED. AND SURG. REPORTER:—

On October the 9th, while practising at Red Wing, Minnesota, I was called out to the Goodhue County Poor House, situated three miles outside the city, to examine Edward Bean, a tramp who had recently been admitted and who could or would give no clear account of himself. I found a stout, well built, dissipated-looking Irishman, who gave his age as fifty-six and occupation laborer. He complained of vague pains in all parts of the body, headache, dizziness, and ringing in the ears. I had received no intimation that the man was blind or nearly so, but my attention was immediately drawn to his right eye, the pupil of which was dilated to such an extent that only the narrowest rim of iris was visible, while in the left the opposite condition presented itself, the pupil being contracted to the size of a small pin-head. Closer inspection revealed opacity of both lenses, vision in the left eye being limited to the bare perception of a strong light, while with the right he could distinguish objects, but not their forms. The extreme dilatation of the pupil of the right eye was not caused by the use of atropia, as I first thought, nor would the iris of the left respond but feebly to this drug; for though I repeatedly instilled a four-grain solution and afterwards an eight-grain solution, the dilatation was slight, but perfectly even, showing there were no iritic adhesions. There was further (in the left eye), an enormous collection of aqueous humor, a real dropsy, so to speak, pressing the lens backwards and giving rise to extreme tension. This may have been partly the cause of the iritic sluggishness. Having decided to operate on the left eye, I at once put my patient on quinia, whisky, and a generous diet, and on the 15th I proceeded, assisted by Drs. Leininger and Mogstad, to extract

the lens. Dr. Mogstad, who examined his heart, having found that organ diseased, we decided to use ether in preference to chloroform; but he took it badly. For several minutes (at least so it appeared to us) there was cessation of breathing with opisthotonos, only the back of his head and his heels touching the table, while I could have crept under his back. I at once removed the ether, and under protestation of the other physicians, pushed chloroform, until his muscles relaxed and respiration returned. When completely anesthetized, I found, after separating the eyelids, that the superior rectus was spasmodically contracted, drawing the eyeballs upwards and hiding the entire cornea under the upper lid. The proper thing to have done under these circumstances would undoubtedly have been to make the incision in the lower margin of the cornea and extract downwards; but becoming somewhat excited, I pulled the eyeball forcibly downward with a pair of forceps and held it there while I made my incision, as is customary with most operators, in the upper margin, excised a large piece of iris, ruptured the capsule, and pressed out the lens. There was, as far as I could observe, no escape of vitreous humor, but the removal of the lens, together with the excessive amount of aqueous humor, caused the eyeball to collapse and almost disappear in the orbital cavity. It was perhaps the most bungling operation which has ever terminated successfully. I hurriedly closed the eye, after having instilled a few drops of a saturated solution of boracic acid, and bandaged it firmly, giving orders that the patient must remain quiet on his back. Returning in five hours, I found that there had not only been no pain, but what was still more gratifying to me, the eyeball had regained its natural rotundity, and the patient could, by the aid of a three-inch lens, see my hand. The wound healed readily without any suppuration, and the cornea remained perfectly clear. The after-treatment consisted in the daily instillation of a saturated boracic acid solution. His blind eye is now useful, though vision is far from perfect, owing, I believe, to retinal disease.

I report this case, which may present nothing that is of any particular interest to the specialist, but certainly will prove instructive to the general practitioner or tyro in ophthalmic surgery like myself, if it only reminds him that, when there is spasm of the superior rectus, he does not repeat my mistake, but extracts downwards. This is my fourth cataract operation, with one failure.

JOHN C. SUNDBERG, M. D.

Seattle, W. T.

Hives.

ED. MED. AND SURG. REPORTER:—

Can any of your readers give me any information concerning *hives*? I have now a case under my care of a most aggravated nature, the swelling in some instances involving very large areas; the penis, scrotum, eyelid, and almost every portion of the body, has been in turn invaded. A history of dyspepsia or profound impression of the nervous system usually precedes the commencement of an attack. I have looked through the "*Reporter*" since 1858, and can find no reference to *Hives*. My patient has been under the care of many distin-

guished physicians, and has taken all kinds of drugs, without any benefit whatsoever, the *hives* always remaining until they were ready to go away of themselves.

J. E. F., M. D.

New York.

Another Remarkable Family.

ED. MED. AND SURG. REPORTER:—

In your journal of November 25th, Dr. Morrison, of Maryland, Mo., gives an account of a family of nine children born within a space of eight years, and asks: Who can beat this?

A family recently lived in this place in which fourteen children were born within sixteen years. There were two pairs of twins; all the rest were single births. Eight of the children were born within seven years. W. H. HARWOOD, M. D.

South Malone, N. Y.

NEWS AND MISCELLANY.

Bogus Diplomas.

The editorial in the Boston *Medical and Surgical Journal* upon free trade in diplomas is rarely interesting, and shows that though the medical colleges may often turn out incompetent men, they are in many instances supported by defective State laws. The public are loud in their denunciations of doctors and medical schools; whereas, if microscopical examinations were made of facts, it would be ascertained that those quacks who are at the head of bogus colleges are frequently in collusion with our State Senators, Representatives and other leading men. To think, though, that Massachusetts should be guilty of such high-handed villainy, and that Boston, the "hub," the centre of "culchaw," refinement, intelligence and numerous other virtues, the place of all others, should foster such an institution, is almost too much for us benighted beings to believe. Yet this is all true, and the worst is that the rascals are at large—protected by the State.

The S. D. Gross Professorship.

At a recent general meeting of the resident Alumni of the Jefferson Medical College, held at the College of Physicians, Philadelphia, the following resolutions were unanimously adopted:

Resolved, That, in appreciation of the great services of Professor Samuel D. Gross to medical teaching in this country, a memorial professorship be founded, to be known by his name.

Resolved, That a Permanent Committee of five be appointed, with power to increase it to a number not exceeding nine.

Resolved, That an Auxiliary Committee be appointed by the Permanent Committee, subject to the approval of the Executive Committee, formed of non-resident alumni.

Resolved, That all vacancies in either committee shall be filled by the Permanent Committee, subject to the approval of the President of the Association.

Resolved, That the Executive Committee shall appoint as Trustees of the Fund for the S. D.

Gross Professorship of Pathological Anatomy, a reliable trust company in the city of Philadelphia. That when, in the opinion of the committee appointed by the Executive Committee of the Alumni Association, the sum be sufficient, a professorship shall be endowed on such terms as may be agreed upon by a sub-committee of equal numbers of the Executive Committee and of the Faculty of Jefferson Medical College, in such a manner as will best attain the objects proposed by these resolutions.

Not only the graduates of the Jefferson College, but all American surgeons, will recognize in this action a most fitting tribute to a distinguished colleague—to one who has contributed more to the glory of American surgery, and to the advancement of solid medical education in this country than any other living member of our profession.

The chairman of the committee is Dr. Richard J. Dunglison, who may be addressed P. O. Box 2386, Philadelphia.

Luxation of the Jaw.

The *Boston Journal of Chemistry* is responsible for the following: The late Professor Gibson used to tell a good anecdote in regard to luxation of the jaw: "An old and quite wealthy man came into the office of a surgeon, with a luxation of the jaw, and made motions to have it reduced. The jaw was reduced, and on being asked the fee the doctor mentioned an amount which the man regarded as entirely too much, and insisted on its being reduced one-half. The surgeon said no more about the fee, but began to talk, and pretty soon told a laughable story. The man began to laugh heartily, and out went the jaw. He again made signs to have it reduced, but the doctor said, 'When you pay down my fee, I will put in your jaw.'"

Watermelon Sugar.

A man in Georgia is experimenting with watermelons for the purpose of extracting sugar. His experiments so far, in a small way, induce him to believe that a fair lot of melons contain an average of seven per cent. of saccharine matter, or pure sugar. He estimates that on one acre of good land, suited to their growth, 34,500 pounds of melons would grow, and these would produce, at seven per cent. of saccharine matter, 2415 pounds of sugar, and worth, at ten cents, \$241.50. If this calculation prove correct, our neighboring State of New Jersey, so well calculated for the growth of watermelons, would find the basis for an enormous industry.

The Digestibility of Oysters.

We take the following from *The Proceedings of the Medical Society of the County of Kings*. "Why oysters should be eaten raw is explained by Dr. William Roberts in his lecture on "Digestion." He says that the general practice of eating the oyster raw is evidence that the popular judgment upon matters of diet is usually trustworthy. The fawn-colored mass, which is the delicious portion of the fish, is its liver, and is simply a mass of glycogen. Associated with the glycogen, but withheld from actual contact with it during life, is its appropriate digestive ferment—the

hepatic diastase. The mere crushing of the oyster between the teeth brings these two bodies together, and the glycogen is at once digested without any other help than the diastase. The raw, or merely warmed, oyster is self-digestive. But the advantage of this provision is wholly lost by cooking; for the heat immediately destroys the associated ferment, and a cooked oyster has to be digested, like any other food, by the eater's own digestive powers.

"My dear sir, do you want to ruin your digestion?" asked Professor Houghton, of Trinity College, one day of a friend who had ordered brandy and water with his oysters in a Dublin restaurant.

Then he sent for a glass of brandy and a glass of Guinness's XX, and put an oyster in each. In a very short time there lay in the bottom of the glass of brandy, a tough, leathery substance resembling the finger of a kid glove, while in the porter there was hardly a trace of the oyster to be found.

National Association for the Protection of the Insane.

The National Association for the Protection of the insane and the Prevention of Insanity will meet on January 25th, at the Hall of the College of Physicians, at Thirteenth and Locust streets, in this city.

New York Post-Graduate School.

The New York Post-Graduate Medical School has thus far met with gratifying success. The second term opened January 8th, 1883, and continues until April 28th without intermission. It is hoped that, with its enlarged accommodations, improved facilities for instruction, and increased corps of teachers, it will meet with still greater success.

Smallpox on River Boats.

The steamboats on the western rivers have been in many instances centres of smallpox contagion. To guard against this, the United States Marine Hospital Service has published a circular requesting masters of steamboats to cause their crews to be vaccinated, which will be done by the officers of the service without expense. Directions are also given for fumigating and purifying the vessels.

The Philadelphia Polyclinic.

The Philadelphia Polyclinic and College for Graduates in Medicine presents the following faculty of specialists in medicine and surgery; Dr. R. J. Lewis, operative and clinical surgery; Dr. T. G. Morton, orthopædic and general surgery; Dr. J. S. Cohen, diseases of the throat; Dr. J. C. Wilson, disease of the chest; Dr. William Thomson, diseases of the eye; Dr. J. B. Roberts, surgical anatomy; Dr. C. H. Burnett, diseases of the ear; Dr. M. Longstreth, pathology; Dr. C. K. Mills, nervous diseases; Dr. H. Leffmann, chemistry; Dr. A. Van Harlingen, diseases of skin; Dr. E. L. Duer, diseases of women and children. A clinic will be shortly organized for the gratuitous treatment of the sick poor, and also to afford physicians facilities for advanced instruction in the special departments of medicine.

Statistics Relating to Consumption.

Dr. Playter, of Toronto, has sent a circular letter to a very large number of physicians, asking information on certain points in the histories of the cases of consumption under their care. He received replies from 250 gentlemen, from which he deduces the following statistics: The average age of the patients was 27 years; 46 per cent. were males, and 54 per cent. females; only 28 per cent. were married. The circumference of the chest was in every case much below the average of vigorous persons of the same height, being only $31\frac{1}{2}$ inches; the average height being 5 feet $5\frac{1}{2}$ inches. Persons of such stature should have a chest circumference of about 37 inches. About 55 per cent. had light blue eyes and light hair, and the nervous temperament largely prevailed. Two-thirds of the patients had been engaged in indoor, sedentary occupation, and spent but little time in the open air. Much the greater part of them had slept in small unventilated bed-rooms, two in a bed, had not usually worn flannel next the skin, nor used habitually any form of bath, and nearly all had been small or very moderate eaters, and used but very little fatty food except butter. The general habits of nearly all had been good, and but very few had used alcoholic spirits to excess. In only 36 per cent. of the cases had ancestors died of the disease, while nearly three-fourths had resided in a locality favoring a humid, cool atmosphere.

Dr. Playter draws some important deductions: Marriage in certain conditions and certain stages of the disease is probably unfavorable to the development and progress of consumption. Heredity is not of such constancy and importance as a cause as appears to have been commonly believed, further than in so far as configuration and structure of the body, the relation and the relative size and vigor of the different organs to each other, are influenced by parentage—i. e., in a want of general stamina from defective construction. With the small lungs and consequent imperfect respiratory capacity, the individuals could not consume enough oxygen to utilize the digested products of a generous or full diet, especially that containing much carbonaceous matter; while there would be in all probability accumulations in the body of unused and waste substances which should have been thrown off through the lungs. The one means which will best tend to prevent the development of the disease in those thus predisposed to it is apparent enough; it is that of increasing in early life by judicious physical exercise the size and capacity of the respiratory organs. The doctor draws attention to the desirability of taking into consideration the respiratory capacity of patients suffering from tubercular phthisis before prescribing a full or too carbonaceous diet.

The Philadelphia County Medical Society.

The Philadelphia County Medical Society's officers for the new year are: President, William M. Welch; Vice Presidents, William R. D. Blackwood and Addinell Hewson; Recording and Reporting Secretary, Henry Lefman; Corresponding Secretary, H. A. Wilson; Assistant Secretary, James S. Neff; Treasurer, L. K. Baldwin; Librarian, C. M. Seltzer.

Hunt—Esmarch—Garfield.

On Monday evening, January 8th, before a well-attended meeting of the Academy of Surgery, in the Hall of the College of Physicians, Dr. William Hunt delivered an address in which he severely reviewed the criticism of the management of the case of the late President Garfield, so unadvisedly made by Professor Esmarch. With a great deal of humor, he showed how little the distinguished professor knew what he was criticising, and challenged him to substantiate a case of recovery, after a perforating gunshot wound of the body of a vertebra. He paid a high tribute to Professor Agnew, and satisfied his hearers that from a rational and unprejudiced stand-point, our late President had been treated with the greatest judgment and care.

Koch's bacillus views were reviewed and Formad's opinion of them endorsed.

In the library a large number of microscopes were placed, under which were specimens of Koch's Bacilli, Bacteria of putrefaction, minute fat crystals (which Schmidt of New Orleans claims are the Bacilli of tuberculosis), miliary tubercles, and molecular motion of particles of carbon suspended in water, the so-called Brownian movement. Dr. E. O. Shakespeare exhibited a section of Guiteau's brain, in which the ganglionic cells and neuroglia were well shown. Most of the preparations came from the pathological laboratory of the University of Pennsylvania, and had been mounted by Dr. Formad. A beautiful section of the larynx of a child, showing tubercles, was exhibited by Dr. Carl Seiler.

OBITUARY NOTICES.**DR. A. SELLER.**

Dr. Adam Sheller died at his residence in Mt. Joy, on the 29th ult., after suffering from rheumatism for upward of two years. He was born at the Big Chiques, 1808.

He commenced the practice of medicine in Hummelstown, Pa., from whence he removed to Mt. Joy in 1833. He took a very active part in the Lancaster City and County Medical Society, and labored hard for its advancement, always adhering strictly to the code of ethics.

He was honored and beloved by all who knew him, and his loss is deeply felt by the entire community. He leaves a widow and three children to mourn his loss.

DR. DICKSON.

The death is announced of Dr. Dickson, President of the College of Physicians and Surgeons of Kingston, Ontario. Dr. Dickson began his professional studies at Belfast and Glasgow. He was the first President of the Medical Council of Ontario.

SIR THOMAS WATSON.

This distinguished English physician passed away recently at a very advanced age. From the various notices of his death, we gather that he was not only a celebrated and learned member of the medical profession, but was a *most perfect man*. Half a century ago he wrote his famous "*Lectures on the Principles and Practice of Physic*," which are still looked upon with admiration. He has been

universally accorded the position of leader of the English profession.

PROFESSOR VON BISCHOFF.

The celebrated anatomist, Dr. Theodore Von Bischoff, died in Munich, December 5th, at the age of seventy-six. He has been chiefly famous for his researches on the development of Mammalia. He was the author of several valuable volumes.

HENRY K. SILLIMAN, M. D.

Dr. Henry K. Silliman, who was appointed assistant surgeon of the United States army in 1861, and served in that capacity during the war, died in this city on Monday, January 1st, 1883. He was retired from his office in May, 1867, for disability, resulting from long and faithful service.

Personals.

—The weight of Gambetta's brain was found to be 1100 grammes (38 $\frac{1}{2}$ ounces).

—Mrs. Elizabeth Covington, aged 112 years, died last week at Rockingham, N. C.

—The composer Verdi is to found an hospital at Busseto for the poor of his native State.

—Dr. B. S. Thompson, of Salisbury, Conn., committed suicide at a Cincinnati (O.) hotel by swallowing morphine. Domestic trouble is assigned as the cause.

—Pasteur, the French scientist, is a man of low stature and powerful frame—spare, angular and weatherbeaten. He is a man of few words, abrupt but clear in speech, and of quick, impetuous gestures. Although his fame rests upon minute material research, he is a steadfast believer in spiritualism, and takes no interest in evolution theories or positivist doctrines.

—John G. Whittier, on his 75th birthday, paid a graceful compliment to the poet-physician, Dr. Oliver Wendell Holmes. He said: "There is no man who ought to write much after he is 70, unless, perhaps, it may be Dr. Holmes. He ought to write from now until he is 100. He is charming in everything he writes, and there is such a wonderful variety in his work that it seems a pity he should ever stop."

Items.

—Oscar Wilde is going home to write a book. It will be entitled "American Donkeys with English Ears."

—Hippocrates asserted that "accurate observation of facts, and correct generalizations from them, form the only rational basis of medicine;" and so we are taught to-day.

—During the quarter ended June last, among the deaths registered in Ireland, there were nine reported as those of centenarians. Of this number three were alleged to be 100; one 101; one 103; two 104; one 105; and one 106 years, respectively.

—Another "cure by prayer" is reported from Troy, N. Y. The patient was a young lady, and the disease aphasia and paralysis—clearly a hysterical case.

—Over 140,000 plants are known to botanists, and yet out of the lot the chemists can't make a mixture that will undo in ten minutes the work a hornet has done in two seconds. Does man amount to much?—*Boston Post*.

—The evening primrose and the mistletoe share alike with horsemint and bear's foot the honor of having been recently transferred to the dispensatory as cures for something or adjuvants for something. Even iron-wood has not been able to withstand the knife of the herbalist, while the wild bergamot, sundew and helianthelia have bowed to the fate which places them among the already appalling list of new remedies.

—Chloroform was used by burglars in Wyoming, Del., last week, and a whole family stupefied.

—The Episcopal Hospital, of this city, reports the admission of 1,239 patients during the year 1882.

—Advices from Capetown state that during the past two months 9,000 people at that port have been affected with small-pox, of which number 2,400 died. The further statement is made that all efforts to suppress the ravages of the disease have proved unavailing, which fact is largely due to the objection of the negroes to vaccination.

—A new clinic hall to the Woman's Hospital in this city has been opened.

—The public charitable hospitals of the city of New York contain a total of 5,108 beds, the largest being the Emigrant Hospital with 1,200 beds, the Charity Hospital coming next with 990 beds. The various private hospitals have a capacity of 2,302, and the lunatic hospitals of about 3,000.

—An "emplastrum impermeabile rassicum" is being introduced upon the Continent, which is said to be likely to throw English plaster into the shade.

—At a medical examination, a young aspirant for a physician's diploma was asked, "When does mortification ensue?" "When you propose and are rejected," was the reply.

QUERIES AND REPLIES.

A correspondent desires a *safe* and *efficient* remedy for the removal of hairs from the face, and would like to know if any of our readers have ever tried sulphohydrate of sulphuret of calcium for this purpose.

Dr. B., St. Louis. Dr. H. Clay Whiteford, of Darlington, Md., recommends an infusion of mustard, one teaspoonful to four ounces of boiling water, as a remedy for hiccough. He also suggests a tourniquet over the epigastrium.

MARRIAGES.

GIBBS—MURRAY.—At Howard City, Mich., Jan. 1, 1883, at the residence of the bride's parents, Robert Morris Gibbs, M. D., F. A. A. A. S., of Howard City, Mich., and Miss Mae Murray, of Howard City.

Dr. Gibbs in his first two courses attended the Michigan University at Ann Arbor, Mich. He graduated at Rush Medical College in 1879, after a two years' course at that institution, and in connection with Cook county hospital.

ALVIS—BRIGHT.—Married at the residence of the bride's father, Col. Geo. G. Perkins, in Alma, Ark., December 20, 1882, by Rev. F. A. Jeffett, of Fort Smith, R. H. Alvis, M. D., to Mrs. Belle Bright, late of Jackson, Tenn.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

A chalybeate that has all the virtues and none of the defects of all the present official preparations of iron.

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form iaky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts.,

PHILADELPHIA.

We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instru-
 ments in the world. They range in price from \$15 to \$30, according to the number of currents. 1317-1311

ORIGINAL DEPARTMENT.

LECTURE.

THE INFLUENCE OF CONSTITUTIONAL DIATHESIS ON THE DEVELOPMENT OF DISEASE-GERMS.

BY M. VERNEUIL,

Prof. of Surgery of the Paris Faculty.

GENTLEMEN: It seemed to be the general belief at one period, that it was but necessary for the microbe or morbid germ to enter the organism in order to become multiplied ad infinitum.

The presence of the parasitic germ and effraction of the tissues were regarded as the two conditions necessary but always sufficient to determine infection and constitute the disease.

According to this accommodating theory, no matter what the constitutional condition of the individual, if the malignant charbon bacteride (bacillus) comes in contact with any point where the epidermis is excoriated, malignant pustule will of necessity be developed.

Many observations serve to show that this opinion is not well founded. The organism, in many cases, does not permit the entrance of the virus into the system, and the morbid germ languishes and perishes on sterile ground. Proofs of this assertion are not wanting; of those bitten by a rabid dog, all do not contract hydrophobia; certain individuals escape diphtheria, measles, variola and scarlatina, when exposed to the infection. There are some who do not contract gonorrhœa or syphilis from persons who have communicated the disease to others. I have among my patients a young lady, twenty-three years of age, who has been vaccinated nineteen times ineffectu-

ally. Such subjects are said to be refractory vis-à-vis certain diseases.

On the other hand there are individuals who fall an easy prey to germs, septic or otherwise; if the infectious spores penetrate their tissues, disease is sure to follow. We have just mentioned malignant charbon; the flocks in the pastures of Normandy are hardly ever affected, while its ravages among animals in the neighboring provinces are well known. Finally, one or two successful vaccinations are generally considered sufficient; yet a physician in one of our hospitals contracted small-pox within less than a year after a successful inoculation.

It is evident that but a very slight change in the composition of the solids and fluids of the organism, is necessary to render the system refractory or not to the penetration of germs. What modifications do syphilis, variola, scarlatina, measles, and charbon, provoke in our tissues?

Chemistry cannot furnish a satisfactory reply; and yet, after a first attack, the organism has become improper for the nourishment a second time of the germs of these maladies, which attack but very exceptionally the same individual twice. There are no longer in the economy the same elements or the same quantity of these elements; the constituent principles are so altered that an organism, where certain germs formerly multiplied, no longer receives them.

A laboratory experience, reported by Duclaux in his remarkable work, demonstrates very strikingly the fragility of germs, their nutritive exigencies, and their extreme sensitiveness.

A culture liquid (liquide de culture) contains one fifty millionth part of zinc; one or two gen-

erations of *aspergillus* will completely absorb the metal, so as to render the existence of a new generation stunted or impossible. "In such a liquid a new planting, I was about to say a new inoculation, will remain without effect."

"If we add," continues M. Duclaux, "a sixteen-hundred-millionth part of nitrate of silver to the liquid of culture, vegetation is suddenly arrested. It will not even begin in a silver vase, although chemical investigation cannot demonstrate the presence of any part of the matter of the vase dissolved in the liquid of culture. If we suppose that the *aspergillus* were a human parasite, capable of living and undergoing development in the organism and invading it in all its parts, the quantity of nitrate of silver necessary to eradicate it from the body of a man weighing 60 kilograms would be 40 milligrams. If it attacked only the blood, five milligrams would suffice to arrest the development of so sensitive an organism. It is true that other species may live where the *aspergillus* perishes. Each ferment has a special liquid which favors its development, whence the formula: "Any one soil is not proper for all forms of culture; and a fertile spot is very soon worn out."

The passing or permanent modifications of the organism have then a direct influence on the evolution of the microbic disease. It is evident that certain conditions of the liquids, blood, lymph, etc., facilitate fermentations and cultures; and as the chemical composition of the liquid constituents of the organism vary from one malady to another, it may be advanced, that each constitutional disease, specific or not, renders the organism more apt to contract certain other maladies.

In other terms, the morbid germs find in the liquids of an organism, affected by a constitutional diathesis, a soil either propitious, indifferent, or refractory to their development.

Prof. Bouchard makes a similar declaration in his recent lectures: "Among the agents of infection, there are certain species which prosper in the human organism, no matter whether it be in a state of health or diseased. There are other germs which respect the human subject when in a condition of health, and do not find in the solids or liquids of the organism a soil favorable for their development except under certain morbid conditions, which have induced a deterioration of the economy, in cases where alteration of nutrition has provoked chemical changes in the solids or liquids."

Such an affirmation is perhaps too general and sweeping, but we will seek to determine the

conditions of the organism favorable to the development of certain germs, and obnoxious to others.

The humors or liquids of rheumatic, gouty, and diabetic subjects, charged with uric acid, the urates, or sugar (to mention only recognized chemical products), are very favorable to the development of the microbe of furuncle and anthrax; so much so that the appearance of these local affections should cause the observer to suspect the existence of the arthritic diathesis. It has long been known that anthrax is one of the most common complications of diabetes; but its frequency in gouty and rheumatic subjects and in those suffering from maladies due to defective nutrition (*ralentissement de la nutrition*) has not attracted sufficient attention.

On the contrary, the humors of scrofulous patients are so improper for the development of the furuncle germ, that a case of anthrax in a subject presenting scrofulous manifestations is yet to be reported.

This remarkable antagonism merits confirmation, and furnishes a very interesting subject for study. It must be observed, however, that the infecundity of scrofulous blood as regards furuncle germs is not absolute. Recently we observed a young girl, evidently consumptive, who presented around one knee an eruption of twenty-five furuncles. It is true that both the father and mother of this patient were subject to rheumatic attacks, and she had herself, from time to time, suffered from erratic pains in the joints; so that this case does not form an exception to the general law we have laid down.

M. Bouchard furnishes an example of two other parasites which do not prosper in the human subject, except in individuals affected with certain constitutional diseases, and under the influence of certain well-determined morbid conditions. "The microsporon furfur of *ptyriasis versicolor* has a marked predilection for phthisical and arthritic patients." As regards the *oidium albicans*, it is not developed, as is well known, except in debilitated subjects; during infancy in athreptic children, in old age in worn out and feeble individuals, and at other periods of existence in patients worn out by a grave malady of long duration. Under such conditions, the morbid product appears on surfaces bathed in acid mucus.

Veterinary medicine offers an analogous fact as regards scabies. Delafond and Bourguignon have demonstrated that healthy sheep, properly cared for, resist absolutely colonization by *acari scabiei*, while if these same sheep are poorly fed and be-

come debilitated, they contract the disease very easily. If they are then again brought back to good condition, the disease disappears of itself. Could not we assimilate to these parasites those of gonorrhœa, described by Hallier in 1872, and later by Salisbury, Neisser, Bouchard, and Capitan? This disease would seem to be developed equally well in all subjects; but Ricord, when he gave his famous recipe for taking gonorrhœa, was perhaps wrong in accumulating all the external conditions which might aid in the development of the disease.

The condition of the individual about to be infected is of great consequence. Do we not observe cases where gonorrhœa first comes on with but slight cause, and, finding a fertile soil, becomes chronic and defies all the efforts of the physician? The flow may be arrested, but not completely disappear, and the patient is subject to a new attack on any change of diet, or after any form of excess.

Or, it is by no means an affair of chance, that certain individuals contract such grave and persistent forms of this disease; we are of opinion that the arthritic diathesis is the favorite soil for such luxuriant culture of infectious germs. We have observed many cases of interminable gonorrhœa, developed in individuals who presented all the signs of retarded or defective nutrition, and in such subjects exclusively. Attention to hygienic conditions, appropriate food, hydrotherapy and out-door exercise in the country, often alone sufficed to cure a gleet which had persisted for long periods, in spite of every form of injection and medication.

There is another microbe which has exactly the opposite tendency: I refer to the germ of tuberculosis, the existence of which appears to be fully demonstrated since Villemin proved the inoculability of the tuberculous granulation. This germ does not prosper or spread in the arthritic organism, while it invades and destroys with extreme energy the scrofulous subject. I had long been a unicist, believing in the identity of the scrofulous and tuberculous diathesis. I considered tubercle as forming the most advanced anatomical manifestation of the strumous diathesis, holding the same relation to scrofula as gumma to syphilis, or cancer to arthritism. But many objections to this view presented themselves, such as the coincidence of tuberculosis with cancer, the appearance, rare, it is true, of tuberculosis in subjects who had never presented the slightest trace of scrofula, and finally, the hereditary transmission of scrofula and the evident contagious nature of tuberculosis.

To-day I am of opinion that scrofula and tuberculosis are two distinct morbid conditions; the first due to some defect of nutrition, the second to parasitic invasion. Substituting for the notion of identity that of extreme affinity, the apparent contradictions between the results of clinical observation and those of experimentation, are almost entirely effaced.

It was formerly admitted that a certain degree of antagonism existed between malaria and tuberculosis; to-day opinions on the subject are divided. It is evident there is some fault in the way researches on the subject have been hitherto conducted.

A malarial subject, being considered as a soil for the culture of germs, we should seek whether his organism is favorable or not to the proliferation of the tuberculous microbe; in other words, we should try to determine whether a subject exempt from other disease than malarial poisoning, resists better infection by the tuberculous germ, or becomes more easily its prey. Reciprocally, a tuberculous patient being taken as soil of culture, it will be necessary to determine, in a malarial region, what is his receptivity for the germ of malaria.

It may be, perhaps, at a future day possible to demonstrate: 1st. That soil already sown with paludism (malaria) is not proper for the development of the tuberculous granule, which would prove the correctness of Boudin's opinion; 2d. That on the contrary, the phthisical subject attacked by intermittent fever presents a graver form of the malady and a greater predisposition to pernicious attacks.

As we cannot actually sow and cultivate the microbe in the human subject, the field of experimentation on animals has been largely extended; it is, however, necessary to properly choose soil, favorable or unfavorable, for the culture of the different morbid germs.

These different soils are furnished by the diverse species of animals which sometimes represent with more or less fidelity the principal diatheses of the human species. In order to study, for instance, the points relative to the microbe of gangrenous affections, neither the dog nor cat should be chosen, but the sheep or cow. To cultivate the tuberculous germ, there is no organism prepared by scrofula, but the monkey or calf should be taken in preference to the horse or pig.

Like individuals in a cachectic condition, who are almost without defense against most parasitic diseases, there are certain animals, rabbits, for instance, who receive and permit the development

of all germs, from those of septicæmia to those of tuberculosis, as also the bacterides of malignant charbon. And just as there are certain individuals, who inhabit most unhealthy localities and are exposed to the most fatal epidemics without contracting any disease, even the most contagious, in like manner there are certain animals, the pig, for instance, who remain refractory to all forms of inoculation.

COMMUNICATIONS.

PLACENTA PRÆVIA WITH TWIN PREGNANCY.

BY EUGENE P. BERNARDY, M. D.,
of Philadelphia.

On the morning of June 27, 1882, I was requested to see a case of placenta prævia. The patient, wife of a policeman, was of the blonde order, frail-looking. The history obtained was as follows: This was her fifth confinement; never had any trouble in her previous pregnancies; when about five months had advanced, or about six weeks previous to the above date; she was seized with a severe hemorrhage of short duration; this hemorrhage was easily arrested; she remained free from any hemorrhagic discharge, up to the morning of June 27, when symptoms of labor set in, followed by a hemorrhage, which, according to her physician's account, was fearful. The surroundings amply confirmed his words; the bed was one mass of clotted blood; the mattress was perfectly saturated, the blood dripping through to the floor; the patient blanched; lips perfectly white, pulse weak and thready. Stimulants were at once ordered and the head lowered. On examination, I found that the attending physician had partially detached the placenta from its connection with the os, a portion being still attached to the right side of the uterus, from which the detached portion was hanging into the vagina. The condition of things showed plainly that the case was one of complete placental presentation (placenta centralis). The head of the child presented in the left anterior position, filling the cavity, and pressing on the placenta prevented any further flow of blood. Ergot having been given in the early stage of labor, was now acting strongly, and in a short time a child was born. On pushing my examination to discover the site of the attachment of the remaining portion of the placenta, I discovered another bag of waters, which I ruptured; the child presenting by the feet, I made traction, and soon delivered the patient of a female child, dead, the first being a male child,

also dead. The second child was larger and *healthier* than the first, and seemed to have died during the labor, while the first child was very small and looked younger than its mate.

I supposed at first that there was a common placenta, but on extracting the presenting placenta, I found that there was a second placenta situated in the upper right fundus of the uterus, thus giving to each child its own placenta and amniotic pouch.

In publishing the above, I do so on account of the occurrence of this complication, and in searching for recorded cases, I have not been able to discover any.

CALX SULPHURATA.

BY JOSEPH MIXSELL, M. D.,
Of Philadelphia.

This new official of the United States Pharmacopœia of '80 has been accorded a place among the better known lime compounds rather in deference to its adopted title than through any therapeutic relationship.

Although but lately known to some of the profession, it has since 1874 been extensively employed by those of us to whom "Ringer's Handbook" is a guide. As is usual with all novelties, its earlier advocates in America claimed extravagant results from their employment of it, and in due time were followed by a host of imitators, who, encouraged by its praises in the journals, placed it upon trial in their own hands, and finding fewer or no results of a curative character, condemned it as useless. This disagreement led to its careful study by the members of the Therapeutic Society of New York City, whose report (*N. Y. Med. Journal*,) is somewhat meagre and unsatisfactory. That much of the uncertainty attending the use of this remedy was due to the varying quality of the drug itself, and methods of its administration, there can be but little doubt.

Upon its first introduction, under the chaperonage of Sidney Ringer, no rules were laid down for its preparation; hence prescribers who desired to administer the substance were obliged to depend upon the dispensing chemist's idea of what compound of sulphur and lime was proper. Manufacturers of gelatine-coated pills speedily placed before the trade an agreeable form of this bad-smelling substance; no one, however, was found ingenious enough to devise an "elixir."

It will be found upon careful examination—and the writer's experience confirms the assertion—that nearly all who have administered this drug with success have obtained their results from its

original form of artificial preparation, viz: as a "trituration" of the freshly-prepared combination of "*finely-powdered clean oyster shell and quite pure flowers of sulphur, heated together to a white heat for ten minutes in a crucible hermetically closed.*" (Hughes' Pharmacodynamics, London, 1876.)

There is every reason to believe that the result of this combustion would present a much more complex series of chemical decompositions and recombinations than the simpler formula of the present Pharmacopœia; and in view of the disparity of results obtained by its "provers," it might be well to follow rigidly in the footsteps of those whose success was evident enough to provoke imitation.

That the preparation is one of a most unstable character is a chemical fact of common knowledge, and this most speedily so when the access of moisture is allowed; the presence of water originating chemical reactions which after a time reduce this loose combination of sulphur and lime into an inodorous and insoluble mixture of gypsum and calcic carbonate.

It is also to be remembered that in its natural and most familiar mode of administration—that of the sulphur waters—the amount taken into the system at each dose is comparatively inconsiderable; the curative dose of the artificial preparation is likewise limited, Ringer and Hughes agreeing in the maximum dose to be employed—1 to 5 grains of the 1st Dec. trituration (equal in proportion to the solitary official Trituration of the U. S. Pharm., that of Elaterin). This preparation favors the more speedy absorption of its active ingredient, and renders its administration less loathsome; the empty capsules now found in all reputable pharmacies may be utilized in protecting the lips and mouth from immediate contact at the time of its administration, but with an active preparation the eructations are unavoidable.

Many writers of experience claim equally prompt results from the employment of considerably more extensive dilutions of this medicine; this field of investigation is a most interesting one, and deserves more extensive following.

While the therapeutic applications of this remedy at the hands of our own school of medicine have been almost exclusively restricted to its apparent power of either promoting or discussing suppurative action, according to the stage to which inflammation has progressed when its administration is begun, its scope of activity, if the records may be given credence, is much wider—cures of chronic engorgement of the liver, hemorrhoids, skin affections of the *suppurative* or *ulcerative* type,

in scabies, as an adjunct to its use in solution, locally, in affections of the respiratory mucous membrane from croup, to the suppurative stage of pneumonia in blepharophthalmia where the Meibomian glands are involved, ulceration of the cornea and purulent deposits in the anterior chamber of the eye, and in suppurative inflammation of the external auditory canal and middle ear, being claimed as resulting from its use.

As a remedy for common spasmodic or inflammatory croup it is used in its most "attenuated" state—and its administration preceded by the employment of aconite.

EXCISION OF RIGHT OVARY, SUBJECT TO FIBROID DEGENERATION, FOLLOWED BY SUDDEN DEATH ON ELEVENTH DAY.

BY F. HINKLE, M. D.,
Columbia, Pa.

The subject of this operation, Mrs. J. S., æt. 51, widow about ten years, was the mother of three children, all living; youngest nineteen years of age. She enjoyed excellent health all her life, with great regularity of functions, until within the past year. Her labors were all natural, with good recoveries. For about a year her menses had been irregular, and, when present, too free; lasting a week or ten days. She first complained to me of bearing-down pain upon motion, with vaginal prolapse, while I was attending her son in a continued fever, in early part of October, 1882. This I treated with pessaries without affording relief. She said that in going up and down stairs "the womb rolled around like a child's head."

An examination revealed dullness and fluctuation in right iliac region. Bimanual examination by vagina and abdomen showed tumor in same locality, movable, but heavy; womb but slightly movable, and high up. Sound entered somewhat over 3½ inches. Diagnosis: fibro-cyst of right ovary.

The abdomen enlarged rapidly until circumference reached 42 inches. Patient was unable to move about. Urine became scanty until reduced to scarcely more than half-pint each day. There was some œdema of right leg. Resolving to lose no time, I prepared patient mentally and physically for an operation.

On November 27, 1882, assisted by J. Aug. Ehler, M. D., of Lancaster, Pa., F. W. Hinkle, M. D., and Mr. J. A. Meyers, of Columbia, I operated under carbolic spray, and with other customary antiseptic precautions. The patient

came to the table calm and resigned, as was her conduct and bearing throughout the case. When thoroughly under ether, I opened peritoneal sac by median incision about three inches in length. Upon dividing peritoneum on grooved director, about two large bucketsful of ascitic fluid escaped with considerable force. I then found tumor as large as a child's head lying in right iliac fossa, attached by pedicle to right broad ligament. No adhesions; upon puncture with trocar no fluid escaped. To extract it required a slight enlargement of abdominal incision. After securing pedicle with double ligature of Chinese silk, and temporarily with Wells' clamp-forceps, I separated tumor with scalpel. It weighed about four pounds. Previous to extracting tumor I dammed up intestines with seven carbolized sponges. Very little hemorrhage attended the abdominal incision, and none the removal of the tumor. The left ovary I found to be normal. Having carefully removed blood, sponges and foreign matter, and finding no oozing, I returned pedicle to peritoneal cavity, after cutting ligatures short, and removing clamp-forceps. Abdominal incision was closed with seven silk sutures so as to leave a straight, firmly-approximated wound. The dressing consisted of a pad of salicylated cotton, covered with several layers of cotton-batting retained by strips of Mead's adhesive plaster, over which was applied a flannel binder. Operation lasted from 11.45 a. m. to 1 p. m.

Patient reacted promptly, and with little sickness from anæsthesia. That evening her mind was clear; skin moist; pulse 73, soft and full; temperature 100.4. Next morning temperature 99.6; pulse 88; respiration 18. Slept $4\frac{1}{2}$ hours during night. Suffered somewhat from pain and flatulence; relieved by 15-drop doses deodorized laudanum every hour, and a hypodermic injection of $\frac{1}{4}$ gr. morph. sulph. and $\frac{1}{80}$ gr. atrop. sulph. After this night temperature did not again rise above 100. It gradually sank until by Dec. 1st—fifth day—it was about normal, and remained so. The pulse, however, grew more rapid and weak. The kidneys secreted freely the day after operation, and continued to do so. She was allowed ice freely, and milk in small quantities.

Third day.—Found patient weak; pulse 108. Ordered beef tea, milk and brandy. That night patient suffered from colicky pains. Relieved by hypodermic of $\frac{1}{4}$ gr. morph. sulph.

Next three days patient rested comfortably and took nourishment as directed. Small doses of deodorized laudanum were given every 3 or 4 hours.

Seventh day.—This morning nurse allowed patient to sleep six hours without nourishment. She awoke weakened. In attempting to stimulate and nourish her again, stomach rebelled. That evening she suffered from nausea and flatulence, relieved by enema of lac. assafœtidæ, castor oil, and chloral. This caused expulsion of large volume of gas with feculent matter. Her stomach sickened whenever food was taken by mouth. Ordered nourishing enemata every four hours, of egg, beef tea, brandy, and quiniæ sulph., with opiates as needed. During progress of case she did not receive more than six or seven grains of opium.

Eighth day.—Patient cheerful, and rested quietly. Still nourished by enemata. Pulse 120. Bowels moved during night. Examined incision under spray. Found it united firmly except a small portion at lower part. No suppuration apparent. Reapplied dressings as at first.

Ninth day.—Gradually resumed feeding by the mouth in small quantities every two hours; milk, part of soft-boiled egg, milk toast, beef-tea, according to patient's wish. Pulse still remained about 112 and weak, but there was no marked prostration; extremities warm, appearance cheerful. The bowels moved several times on ninth and tenth days, apparently provoked thereto by the enemata. When rejected, these were repeated until retained.

Eleventh day.—I had intended to remove the sutures on the afternoon of this day. At 9:00 a. m., found patient cheerful, and resting comfortably. Two hours afterwards found her speechless, with cold hands, covered with profuse perspiration. Her feet remained warm, and lips were not markedly blanched. Breathing rapid, 32–36, and irregular. Pulse 120, weak. In spite of active stimulation with heat, brandy, ammonia, and digitalis, she died at 2:20 p. m. Circumstances made a post-mortem examination unadvisable. The incision was firmly united in its entire length. Abdomen flat and natural in appearance.

Patient's death was a great surprise to me. There were no signs of inflammation or of secondary hemorrhage. She at no time manifested signs of weakness that alarmed me. Death may have been due to heart-clot, or to a general failure of nervous system under the magnitude of the operation, remote shock.

I should be pleased to have the opinion or experience of others in similar accidents, or any information to throw more light upon this unfortunate termination of an otherwise well-progressing case.

FRACTURE OF THE THYROID CARTILAGE.*

BY CHAS. E. SAJOUS, M. D.,
Of Philadelphia.

In the July number of the *Archives of Laryngology*, I reported two cases of fracture of the thyroid cartilage. Since then, strange to say, I have again met with a case in which fracture of the left wing had taken place several years before, and which had remained undetected by the treating physician.

The first of these cases was A. H., æt. 43, carpenter, who was brought into the surgical outdoor department of Jefferson College Hospital, in a comatose condition. A deep cut under the chin was the only visible injury, and this giving rise to profuse hemorrhage, hæmostatics were applied and the edges of the wound united by stitches. As soon as able to speak the patient complained of great pain in the throat, and expressed astonishment at the character of his voice, which had completely changed: it had become very low in pitch, and any attempt to raise this would greatly increase the pain. Dr. Joseph Hearn, chief of the clinic, upon examining the throat externally, detected distinct crepitation in the left wing of the thyroid cartilage, applied adhesive strips, and referred the case to my department.

While walking on a row of large dry-goods boxes in a dark cellar, Mr. H. had not noticed that one of these was missing, and upon falling into the open space, struck his chin against the edge of the box before him. He felt as if the front of his neck had received a violent stretch, and after that lost his senses. He was found in this condition and brought to the hospital.

A few hours later the patient became completely aphonic; the jaws could only be separated with great difficulty; the act of swallowing produced intense pain. By this time, also, the neck had become swollen to a marked degree, although no particular line of tenderness indicated that the neck proper had struck against the box. Pulse 94, temperature $101\frac{1}{2}^{\circ}$.

During the evening, breathing became difficult, sufficiently so to induce me to prepare for tracheotomy. It was impossible to introduce a mirror to examine the larynx. The pulse by this time had risen to 106, and the temperature to $102\frac{1}{2}^{\circ}$. I ordered mustard foot-baths, and applied a blister on each side of the neck, expecting by derivative action to decrease the congestion or œdema in the parts. Noticing a slight improvement, I ordered a drastic purgative (elaterium), which caused four liquid stools.

The next morning the patient was much better; the dyspnoea was but slight, and the pulse had decreased to 90; temperature 100° . The swelling had somewhat declined, but the pain was as severe. Crepitation was easily felt in the left wing of the thyroid cartilage, the line of fracture following, as far as I could judge, that existing between the insertions of the sterno-thyroid and thyro-hyoid muscles. My treatment merely consisted in maintaining the parts in proper apposition, and anodynes internally. It was not, however, before two weeks that the patient was able to make his voice audible, or to open his mouth sufficiently to enable me to introduce a mirror. I found the larynx somewhat congested, but otherwise normal.

I saw him four months later and found the crepitation as marked as immediately after receiving the injury. The voice had remained rather weak, but was natural in tone.

The second was C. P., æt. 31, contractor, who came to the throat clinic suffering from subacute laryngitis. In examining his throat externally I felt distinct crepitation in the left wing of the thyroid cartilage, just below the base of the superior cornu. Upon asking him if he knew anything about the origin of this condition, he told me that, two years before, in a spell of violent coughing lasting three hours, he felt as if something had broken in his throat with a snapping noise, followed by severe pain and swelling of the neck. This continued for a week, then gradually subsided, leaving a sensation as if a foreign body were in the larynx. Laryngoscopic examination revealed nothing, and the fracture did not seem to interfere with any of the functions of the larynx.

The third case was that of a man aged 33, who had come to the clinic to be treated for chronic laryngitis. While palpating in the region of the larynx, externally, I detected distinct crepitation in the left wing of the thyroid cartilage. Upon investigating its origin, the patient told me that he had received a kick from a horse, the tip of the shoe striking the chin. This caused a fracture of the lower maxillary bone, and a deep incised wound, the cicatrix of which was plainly visible. He stated also that "breathing had been rather difficult" during the first week after the accident, but that this symptom had been ascribed to the general inflammation which involved the whole buccal cavity.

Injuries of this kind are of extreme danger to life, in consequence of the respiration being obstructed, either immediately after the injury from displacement of the ends of the fracture, or

*Read before the Philadelphia Laryngological Society.

subsequently from very extensive local or general emphysema, or from inflammation and œdema of the lining membrane of the larynx. In 62 cases collected by Hénogue and Durham, 50 died and 12 recovered. Of 27 cases analyzed by Dr. Wm. Hunt, of this city, including one observed by himself, 17 died.

In the three cases described above, close examination developed the fact that the fracture in each case was incomplete, and that the want of serious symptoms was due to that fact.

The lower margins of the cartilage could be felt distinctly, and their resistance to pressure indicated their normal condition. The cricoids were of course uninjured.

These cases, added to those collected by Hénogue, Guerlt, Nelaton, Durham, and Hunt, lead me to think that a fracture of the thyroid cartilage can occur without giving rise to serious symptoms, when that fracture is *simple* and *incomplete*, and that the prognosis and indications for treatment are in accordance with the extent and location of the fracture. This deduction leads me to differ with Hüter, who says that "as soon as fracture of the larynx has been diagnosed, tracheotomy should be performed, and that even in cases where the diagnosis is not quite certain, the operation should nevertheless be carried out." I would then suggest that when the fracture does not involve the lower margin, then tracheotomy should be deferred until alarming symptoms should supervene; but that when it involves the lower margin or the cricoid, it should be performed at once.

HOSPITAL REPORTS.

UNIVERSITY HOSPITAL.

CLINIC OF JOHN ASHHURST, JR., M. D.,

Professor of Clinical Surgery in the University of Pennsylvania.

Reported by LOUIS J. LAUTENBACH, M. D.

Case 1.—Moist gangrene of leg.

Case 2.—Fracture of thigh bone.

Case 3.—Intro-external hemorrhoids: Operation by ligature.

Case 1. Moist Gangrene of Left Leg.

Our first case this morning is a very interesting one. The man came to our hospital last Wednesday with the history of an injury received by the fall of a pile of lumber two or three weeks before. For some time after the injury he was treated at home by Dr. Rowland, of Media, and at first did well. He was treated by irrigation, which is an excellent application in cases of severe contusion. In a few days, however, despite the treatment, the limb began to swell and then dark spots began to appear, until the condition was produced which is now present, and which we recognize as gan-

grene. There is no positive evidence of fracture here, although, on account of the condition of the soft parts, we have not been able to make such a thorough examination as to render it certain that there is no fracture.

There are different forms of gangrene, the most important division being into the dry and the moist varieties. In the *dry* form of gangrene, which occurs usually in the aged, and is then called senile gangrene, there is a diminution of, and then an arrest in, the arterial supply, while the blood in the veins returns to the general circulation. In old people this is caused by the fact that the arterial tissues at that time of life frequently have undergone a greater or less degree of calcification or of atheromatous change.

If the stoppage of the circulation occurs quickly, then it gives rise to *moist* gangrene. Venous obstruction almost invariably gives rise to this form of gangrene; of course with the venous obstruction there may be arterial obstruction as well.

Numerous large openings have been made in different parts of the limb, to relieve pressure and thus prevent the spread of the gangrene. Certain portions of the leg appear to have been thus preserved, and are apparently healthy. Washing the limb, we notice one of the characteristics of gangrene, the separation of the cuticle; this, in doubtful cases, may serve to distinguish threatening gangrene from ecchymosis due to simple contusion.

We now see a line between the dead and living tissues, which, however, is not the line of *separation*, though we hope that it will prove to be the line of *demarcation*. The line of separation, at a later period, replaces the line of demarcation; it is a line of granulation. It is a mistake to suppose that the dead and living parts are separated by the process of ulceration. The separation in gangrene is effected by the same process as the separation of the sequestrum in cases of necrosis; the dead tissue is pushed off from the living parts by underlying granulations.

When the line of separation forms, that is the time at which we feel that an operation is justifiable. In the large majority of cases of gangrene, it is not justifiable to operate before this line forms. There are however cases where it is not only justifiable, but where we are compelled to operate at an earlier period. When you see a case of what is called *true traumatic or spreading gangrene*, which occurs most frequently as a result of compound fracture or of a severe lacerated wound, immediate amputation may afford the only chance of recovery. The worst case of this kind which I have ever seen was in a man who had been torn by a lion's claws, and in whom gangrene set in almost immediately, spreading rapidly to the trunk, and causing death in less than 48 hours.

When our patient was brought here Wednesday evening, he told us that the gangrene had existed for several days, with great swelling above the knee, which had somewhat subsided. There being no urgent need for an operation, we concluded to wait and observe the case, and thus found that the gangrene was not disposed to spread beyond its existing limits. Had we operated immediately on the patient entering the hospital, we should not have known at what point to amputate, and the additional injury necessarily inflicted by the

operation itself would have probably increased the tendency to gangrene and have led to the sloughing of the flaps. If, however, while watching the case we had found the gangrene spreading rapidly above the knee, then we should have operated immediately, as no line of demarcation would have been likely to form, and we should have known that as soon as the gangrenous process had involved the trunk a fatal issue would follow almost immediately. Under such circumstances an operation high up in the thigh would have been imperatively demanded. We have lately had a patient in the house who sustained a severe contusion of the arm with fracture of one of the condyles of the humerus, and who was treated by irrigation with a very favorable result. When he was almost convalescent, he was suddenly attacked with violent pain in the limb, with great swelling and high fever, and large patches of gangrene showed themselves around and above the elbow. So suddenly did these symptoms occur, and so rapidly did the gangrenous process spread, that although in the afternoon very long and free incisions were made, amputation was imperatively required the same night, and was promptly performed by Dr. Wharton. Undoubtedly this timely performance of the operation saved the man's life; had amputation been postponed, the patient would probably have died before morning. In all cases of this rapidly-spreading form of gangrene, it is your duty to operate at once.

Other forms of gangrene are of interest. There is a form of gangrene which is met with rather in military surgery than in civil, where a ball passes through the thigh, high up, injuring the femoral artery. In these cases the rule of Guthrie is a sound one. Guthrie says that while the gangrenous process is limited to the foot, below the ankle, you should wait; you are justified in waiting till the process has extended above the ankle. If however, it has extended above the ankle, experience shows that the process does not commonly stop until just below the knee. Under these circumstances amputation is to be performed at the "point of election," a short distance below the tubercle of the tibia. By this means we can give the patient a good stump, and save a great deal of time and suffering.

In senile gangrene, which is a result of atheromatous or calcareous degeneration of the arteries in the old, you had better not operate at all. If amputation is performed above the apparent limit of gangrene, it is almost certainly followed by a recurrence, of sloughing in the flaps, and death eventually ensues. It is much better to use simply deodorants and antiseptics locally, when the dead part, if small in extent, may occasionally be spontaneously separated. The late Mr. James, of Exeter, England, advised that in cases of senile gangrene amputation should at once be performed high up, at the upper third of the thigh; but it is evident that while we cannot say that such an operation is absolutely necessary, it exposes the patient to very great risk; it is a very dangerous operation, especially in old people, and in the large majority of cases the result is fatal. The best thing to do, therefore, in these cases, is to wait, when, if the part separates, the bone can be resected so as to give a better stump without performing a regular amputation.

For deodorizing a gangrenous limb, nothing is better than charcoal, which mechanically absorbs gases. This can be used simply in the form of powder, or in connection with ordinary poultices, or with the fermenting poultice, made either with yeast or with porter.

[This patient was again brought before the class a week subsequently, when, the line of separation being fully formed, the limb was amputated above the knee. The patient bore the operation well, but some days afterwards began to fail, and although the greater part of the stump healed by adhesion, death from exhaustion followed ten days after the amputation.]

Case 2. Fracture of Thigh.

This man, beyond middle age, was brought here with a fracture of the shaft of the left thigh bone. On his admission we found the limb to be from $\frac{3}{4}$ to 1 inch shorter than the other, with decided eversion of the knee and foot, and with well marked crepitus. He has been under treatment for ten days, and everything has been going on well. There is now less than a $\frac{1}{2}$ inch shortening, with the bones in good position, and the limb quite straight. We have had here but very slight effusion into the knee joint, much less than is usually present in injuries of this kind. Effusion into the joint makes the patella float; by pressure it can be pushed down, but when the pressure is removed it rises. This symptom is almost universally present in fractures of the shaft of the thigh bone. The correct explanation of this symptom has been given by the French surgeon Gosselin. The blood which is poured out in the neighborhood of the fracture gradually finds its way to the outer side of the synovial membrane, causing by irritation a subacute synovitis and consequent effusion into the joint. This effusion usually occurs some hours or even days after the injury, and lasts one or two weeks. It is important that you should know that this effusion is dependent on the fracture of the femur, and is not an evidence of injury of the joint itself, as otherwise, when the knee begins to swell, you may be blamed for having overlooked a lesion which it will be thought you ought to have discovered.

The swelling of the knee is of no consequence, except as influencing the mode of dressing. Some surgeons in applying the extending bands in cases of fractured thigh, carry them up to the seat of fracture, and secure the ends by a circular band above the knee; then, if swelling of the knee occurs, some pain is caused. This is one of the reasons why I do not carry the extending bands above the knee. I have no faith in the doctrine that extension thus applied stretches the ligaments of the knee joint. The extending bands pull evenly upon the skin and all the tissues of the limb, and there is no reason why the extension should be specially transmitted to the ligaments.

These cases, as you know, are almost invariably treated by extension; the weight or amount of the extending force varies much in the hands of different surgeons. You will generally find that two or at most three bricks are sufficient; a brick weighs about four and a half pounds, so that from nine to fourteen pounds is about the weight usually required. We should begin by using one brick,

causing slight extension, keeping the leg in position and decreasing the tendency to muscular spasm, afterward adding a second brick, and perhaps a third. Some surgeons use very heavy weights, ranging from twenty to thirty or even forty pounds. This I do not think at all necessary, and the use of such powerful extension is liable to cause delayed union, or even non-union. With regard to the occurrence of shortening after fracture of the thigh, I may say that as far as my experience goes, shortening occurs after all fractures in adults. The union or healing of the two ends of a broken bone has been not inaptly compared to the mending of a broken piece of sealing wax; before the broken ends can be united, they must be melted, and in the process of melting a certain amount of length is lost. The extremities of the broken bone are softened in the formation of granulation tissue, which then goes through the different stages of callus, and finally is replaced by new bone. In adults, a certain amount of shortening is, I believe, unavoidable, though it may be very slight. In children, instead of a diminution of length we may have even an increase; the transmitted irritation develops to an exceptional degree the bone-producing power of the epiphyseal cartilages, and there is thus a positive hypertrophy as regards length; while, as far as the fracture itself is concerned, there is shortening. This hypertrophy we do not have in adults, as the bones have in them already attained their proper growth.

In order to maintain the limb in its proper position, we require to fix the adjacent joints. When a joint is involved, one of the objects of treatment is to fix the bones above and below the articulation. In this case we want to fix both the knee and hip joints, and to accomplish this I like a long splint—either a Liston or Desault splint, with the foot-piece left off. This is then simply a long piece of board extending from the axilla to just below the foot, with another shorter piece reaching from the scrotum to the inner malleolus. These are either padded or simply wrapped in a splint-cloth, long bags filled with bran, called junk bags, being placed between the splint and the limb. To explain why these bags are called junk-bags, several explanations have been offered; one of them is that the name is derived from the French word "*junc*," meaning a reed, a rush; the idea being that the early surgeons used in their treatment splints made of reeds; another explanation is that the word "junk" is a corruption of the bags being used to assist the "junction"—joining of the bones. I prefer the long splint and junk-bags to sand bags, when the fracture involves the shaft of the bone. In these cases, there is always a tendency to bowing outward of the limb, to prevent which requires firmer lateral support than can be given by the sand-bags alone. In fractures of the neck of the bone, however, where lateral support is not so necessary, the sand bags answer every purpose. We need under the tendo-Achillis a little padding to keep the heel off the bed, after which, the junk-bags being pressed in position by the splints, strips of bandage are fastened across to keep these together. We generally use five of these strips; three for the limb—one at the uppermost part of thigh, one at the knee, and one at the ankle; and two for the body, one around the

thorax, and the other around the pelvis. We are in this case obliged to dispense with the pelvic band, as the patient has such a huge belly that we cannot adjust it properly. The extension should be so arranged as to keep the limb somewhat abducted from the line of the body.

Case 3. Intero-external Hemorrhoids: Operation.

Our next patient is a man who has had hemorrhoids for a number of years and at one time lost considerable blood from them. Though there has not been much hemorrhage lately, yet he is very pale and anæmic. Examination of the rectum leaves no doubt that he is suffering from piles, and there is no evidence of visceral disease or other contra-indication to an operation.

The needle which I usually employ for the ligation of hemorrhoids is that known as Bushe's, by which the pile can be transfixed from above downward; but as that instrument is not at hand, I will use instead an ordinary nævus-needle.

Hemorrhoids, or piles, are of several kinds. The most important division is into external and internal hemorrhoids, or, as they are also called, sub-cutaneous and sub-mucous.

The sub-mucous or internal piles are found within the sphincter, while the purely sub-cutaneous are outside the sphincter. In many cases, hemorrhoids are neither exclusively internal nor external, but partake of both characters; and are then called intero-external, being covered partly by skin and partly by mucous membrane.

The treatment differs somewhat according to the nature of the hemorrhoids. The purely external piles it is perfectly safe to cut off with scissors, and usually we have no hemorrhage. If hemorrhage should occur, it can be arrested by an ordinary ligature. Purely internal hemorrhoids it is safer to tie, and not to cut. If the hemorrhoids are half internal and half external, which seems to be their nature in this case, then it is safe to tie them and cut away the protruding portions. The hemorrhoids are tied by transfixing them with a needle carrying a double ligature, which is then cut in two, so that the pile may be strangulated in two portions. Before tightening the knots, a groove is cut through the skin, so that the patient may suffer less pain after the operation. Having tied both ligatures, the projection is cut away.

Before the patient gets from under the influence of ether, an opium suppository will be inserted into the rectum, and the only dressing required will be a simple piece of wet lint. The ligatures will come away in from seven to ten days, leaving small ulcers, which will readily heal; the healing may be hastened by touching them with the stick of nitrate of silver. A frequent sequel of this operation is retention of urine. In order to prevent this to a certain extent, I always thoroughly stretch the sphincter either before or after applying the ligatures.

BELLEVUE MEDICAL COLLEGE, NEW YORK.

CLINIC OF DR. LEWIS A. SAYRE.

Fracture of the Clavicle in its Outer Third.

GENTLEMEN: I here present to you, a case which is of considerable interest (the patient was now placed before the class and his upper garments

removed), although it hardly comes under the chair of orthopedic surgery, unless considered as a prevention of deformity.

This young man informs me that a few days ago he fell from a wagon, striking upon his shoulder, and which, you perceive, has resulted in a fracture at the outer third of the clavicle; you note how my finger drops into the depression at this point, and how extensive the discoloration of the tissues. Now, in these cases the shoulder drops downward, forward and inward, the pectoralis

Fig. 1.

major drawing it downward and forward, while the sterno-mastoid, drawing the sternal end of the clavicle upwards, results in the deformity which you see here. I suppose there have been more instruments devised for treating fracture of this little bone than all the instruments for other fractures put together. I cannot take time to enumerate them; but two or three years ago Dr. Frank Hamilton occupied three consecutive lectures in applying these various methods (before the class) upon the patients admitted to the hospital for fracture of the clavicle, and then concluded his exhibition by informing the class that all of those methods were of no avail, and he would not advise their use, but stated that the patient should be placed in bed with a pillow between the shoulders so as to bring them well back, the patient to remain perfectly quiet; this treatment he considered all that was necessary, and termed it postural treatment. If a man can lie absolutely still for six weeks, a union might be effected in this manner; but the deltoid muscle and muscles of the shoulders would probably move and prevent union of the bone.

My plan of treatment is simply this: I take two strips of adhesive plaster two and a half inches wide, then passing one strip of adhesive plaster around the arm at the junction of the middle and lower third, I make a loop, leaving an open space at the posterior part of the arm, as you see: this prevents strangulation. Then drawing the arm back, I bring the pectoralis major upon the stretch, but the acromial end of the clavicle still

rides under the sternal fragment; I now secure the arm back by passing the strip of adhesive plaster around the body, bringing it under the arm of the opposite side, across the thorax, and fasten it to itself on the back.

Care must be taken not to draw the arm too far back, but just sufficient to put the pectoralis major upon the stretch. I now take this other strip of adhesive plaster, and make a slight longitudinal cut in the centre to admit the point of the elbow; you now flex the arm at an acute angle over the chest, drawing it upward, forward, and inward, and in this manner you reduce your fracture, as you can see that I have done in this case. Bringing both fragments of the bone into a perfect line, you now secure the arm in this position by passing the strip of adhesive plaster over the elbow across the back diagonally to the opposite shoulder, then bring the anterior end of the strip up along the arm and hand over the chest, and fasten it to itself at the shoulder.

Fig. 2.

I desire you to note this carefully, as it is the most simple method of treating fracture of the clavicle that I have ever seen, and is the only plan of treatment which will yield a perfect result without deformity.

One advantage of this plan of treatment is this; it is absolutely impossible to dress a fracture of the clavicle in a child with any complex bandage satisfactorily, whereas in this your bandage is perfectly secure, and there is no possibility of it becoming displaced. Never use an axillary pad, as the pressure by this means often stops the circulation of the arm and the pain following this occurrence is something terrible.

It is impossible now to displace those fragments as I have dressed this man's injury, and he can go to work with his other hand; if you were to dress that fracture in such a manner as to render that man unable to use his other hand to earn his living, you ought to be compelled to pay for the loss of time which would follow such treatment. I have treated numbers of fractures in this manner with the most perfect results, and I defy any one to detect the point of fracture when cured; I say

that a fractured clavicle can be cured without deformity. Excuse me for my warmth upon this subject, but I have been censured so recently by our own surgeons on this point, that I feel compelled to reiterate my statement somewhat forcibly, and will demonstrate the fact before you in the case now before us, as I intend that you shall see this man when he is cured.

Fig. 2.

[The following week the man appeared before the class; the bandage was found to be in the same position as when applied, the fracture was immovable, and the line of the clavicle perfect.

Two weeks later the bandage was removed, perfect union having been secured; nor was there any deformity perceptible, the fragments having united in perfect line.]

MEDICAL SOCIETIES.

COLLEGE OF PHYSICIANS, OF PHILADELPHIA.

A Resume of Twenty-five Cases of Abdominal Section.

BY J. EWING MEARS, M. D.,

Surgeon to St. Mark's Hospital, Demonstrator of Surgery in Jefferson Medical College, and Gynecologist to Jefferson Medical College Hospital.

[Read December 6, 1882.]

With a view of placing on record the results in a number of cases of abdominal section, and with the hope of contributing to the information possessed already with regard to these operations, I beg to submit the following *résumé* of the cases which have come under my care:

I have endeavored to present the points which were regarded of interest in a concise manner, for this purpose grouping them under different headings.

Of the twenty-five cases of abdominal section, twenty-two were performed for the removal of tumors of the ovary; one was made in a case of encysted dropsy of the peritoneum (reported in the *Transactions* of this college, 3d series, vol. I.); one

in a case of abdominal dropsy, in which the diagnosis was obscure, and an operation of exploration was made; and one for removal of the child in extra-uterine foetation.

As the case of encysted dropsy has been reported to the college, and as I propose, at a future time, to report the one of extra-uterine pregnancy, I shall present on this occasion a *résumé* of the ovarian cases.

Age of Patients.—In the twenty-two cases the age varied from the youngest, sixteen, to the oldest, sixty-five years.

Nationality.—Sixteen patients were natives of the United States, and six of Ireland.

Social Condition.—Five were single, one was a widow, and sixteen were married.

Duration of Growth.—The duration of growth varied from three months to seven years, counting from the time at which the tumor was recognized first by the patient.

Aspiration, or Previous Tapping.—Aspiration, for the purpose of obtaining a specimen of fluid for examination, was performed in eight cases; tapping, to relieve abdominal distension, in four. In one case, in which the cyst was very fully distended by fluid, and the abdominal wall was very tense, leakage followed aspiration, and persisted for some hours, despite the efforts made to control it by pressure. In none of the cases in which aspiration or tapping was performed did any serious results occur, nor were there any evidences, in the operations which followed, of complications due to the previous aspiration, or tapping. In all cases, proper precautions were taken, the patient being required to rest in bed from three to four days subsequent to the operation.

Condition of the Patients at the Time of Operation.—With the exception of two, who were the subjects of malignant disease of the ovary, the condition of the patients was good. All were placed upon preparatory treatment, extending over periods varying from two weeks to two months.

Line of Incision.—In all cases the abdominal cavity was opened by incision in the linea alba, midway between the umbilicus and pubes, the length of the incision varying according to the nature of the tumor and the presence or absence of adhesions. A simple, mono-cystic, non-adherent growth was extracted easily through an opening one and a half inches in length; whilst other tumors, polycystic in character, with numerous and strong adhesions, required incisions from four to six inches in length in order that the hand could be introduced into the abdominal cavity, so as to sweep over the external surface of the tumor for the purpose of detaching adhesions, and also into the interior of the growth to disintegrate its contents, and thus reduce its size. The incisions were invariably closed by the introduction of metallic sutures—iron or silver wire—the needle being carried so as to include the peritoneum.

Adhesions.—In eighteen cases adhesions, either parietal, omental, or visceral, existed—differing greatly as to extent and character. In some instances they were so slight as to be separated readily with the finger; in others, they were very extensive and very firm, requiring some force to effect their detachment, and exposing denuded, bleeding surfaces. In one of the fatal cases, the adhesions were universal, and so firm as to require

a minute dissection to be made, in order to effect removal of the cyst.

In a second case, a portion of the parietal surface of the peritoneum as large as the palm of the hand, and embracing the sub-peritoneal fascia, was detached, leaving a broad band of attachment. This was included in three animal ligatures, and the detached portion removed. During the period of recovery, which was not retarded, the patient referred to the position of the exposed surface as a sensitive point. In still another case, an adhesion, in the form of a cord at least two inches in thickness, and from four to five inches in length, fastened the tumor to the parietes. It was drawn down and a double animal ligature applied before the section was made. Hemorrhage caused by the separation of adhesions has been controlled by the application of carbolized silk and animal ligatures, both ends being cut short, and the ligatures permitted to remain "*in situ*." In some instances, torsion of the vessels has been sufficient to restrain the bleeding.

Character of the Cysts.—Four cysts were unilocular, sixteen were multilocular, and in two, malignant disease existed. In one of the latter, medullary cancer involved both ovaries, and in the other colloid disease was present.

Double Ovariectomy was performed in two cases.

Primary or Secondary Operation.—In one case the operation was secondary, ovariectomy having been performed thirteen years previously. In this instance the incision was made to the side of the cicatrix of the primary operation, so as to avoid wounding the pedicle of the tumor removed, which was found to exist as a small cord attached to the inner surface of the abdominal wall, and to be of such length as to permit the uterus to occupy a normal position. Elongation and shrinkage of the pedicle has been observed in *post-mortem* examinations made, in cases in which death occurred some years after ovariectomy.

Treatment of the Pedicle.—In all but one case the pedicle was secured by the application of the clamp; in the case excepted, a carbolized catgut ligature was applied, both ends cut short, and the pedicle was returned to the abdominal cavity. In cases of very short pedicles I have been able always to secure them with the clamp, and in no case was it observed that traction made to accomplish this produced any harm. In one instance of an extremely short pedicle, where, in fact, the wall of the cyst was separated not more than a half inch from the uterus, a double animal ligature was applied, which failed to control the hemorrhage. The clamp was then applied over the ligature, bringing the uterus well up between the edges of the incision. Although the patient had a tedious convalescence, the ligature and clamp came away in good time, and the abdominal incision healed kindly. Beneath the cicatrix the uterus could be distinctly outlined, and after the return of the patient to her usual duties no complaint was made of pain caused by traction upon the organ. In one case only was there noticed a slight tendency to the occurrence of ventral hernia, and this in a young patient who slipped and fell on the icy pavement a short time after recovery from the operation. A good deal of tension of the abdominal walls was felt in the act of falling, and it was thought a slight detach-

ment of the pedicle had occurred. Rest in bed for a few days, with pressure over the cicatrix, relieved the condition.

In nearly all of the cases in which the clamp was applied, it was observed that it could be removed safely at about the same time with the last of the sutures, and, therefore, the healing of the abdominal incision was not materially delayed. In one or two cases both sutures and clamp were permitted to remain longer than usual. In favorable cases the first of the sutures was usually removed on the sixth day, and the clamp on the eighth or tenth.

In three cases menstruation has occurred by the pedicle. In all of the cases it took place but once, and did not produce any serious inconvenience. It occurred in one of the cases in which double ovariectomy was performed, two clamps having been applied to the pedicles without difficulty.

Strangulation of the intestine has been noted as being due to the use of the clamp. In my observation of the cases of others, and in my own, I have not met with an accident of this nature. As it has followed likewise the use of the ligature, it cannot be ascribed alone to the employment of the clamp.

The support afforded to the uterine by the attachment of the pedicle to the abdominal walls has seemed, in some of the cases, to have been of benefit, overcoming displacements which were productive of much previous discomfort.

In one of the three fatal cases which occurred, the ligature was applied and the pedicle returned to the abdominal cavity; death resulted on the third day from septicemia, and the autopsy showed the stump of the pedicle softened and covered by a grayish slough. This condition of the pedicle was, I think, not a primary condition, but was a part of the general inflammation which pervaded the abdominal cavity, occurring in a case in which the cyst was adherent in every part to the parietes and viscera, and which required minute dissection to effect its separation.

While the tendency of the present day is to return to the use of the ligature as an exclusive method of treating the pedicle, I think it unwise to discard entirely the clamp. The imbedding of the ligature and its subsequent absorption demand a degree of reparative power, which some much debilitated patients do not possess; in such cases it would appear proper to employ the clamp.

Drainage.—In one case it was thought desirable to secure drainage of the abdominal cavity after operation. For this purpose a large perforated rubber tube was introduced and allowed to remain in position for three days. During this period no fluid escaped, and the symptoms presented by the patient gave no indication of the collection of septic fluids. Of the great value of drainage after ovariectomy there can be no question. Its use is especially indicated in cases in which adhesions of some extent have existed.

Antiseptic Precautions.—In fourteen cases the antiseptic methods were employed in full detail at the time of operation, and partially during the conduct of the after-treatment, the spray being then omitted. The successful results which have attended some of the cases were undoubtedly due to its use. The condition of the patients during

the after-treatment was favorably influenced, and convalescence was promoted. Of three fatal cases, one occurred after operation under the system. The tendency of most operators at the present time is to employ a modified form of the system, owing to the fear of constitutional impressions made by agents employed. The constitutional effect of the carbolic acid has been observed in two or three cases in the condition of the urine; other than this no symptoms were noted.

It has been stated above that menstruation by the pedicle occurred in three cases. In one a marked impression was made upon the temperature, and the elevation occurring as it did without being accompanied by a corresponding increase of the pulse-rate, attracted attention. On the day preceding the appearance of the flow the pulse was 84 and the temperature normal, 98½°. On the day of its appearance the temperature rose to 100°, and on the third day reached 100½°, then declined to 99½°-99°, and on the day of the cessation of the flow returned to the normal, 98½°—the pulse-rate in the meanwhile remained unchanged. As the elevation of the temperature occurred after convalescence had been fully declared and the patient was within two days of the period when she would have been permitted to sit up, some anxiety as to the cause existed, which was not relieved until its relation to the presence of the menstrual flux was considered.

In two of the cases pregnancy occurred and terminated safely in connection with the development and growth of the cysts. In both, the cysts had attained large size, and notwithstanding the pressure exerted during parturition, rupture did not occur. In one, puerperal peritonitis supervened, causing the formation of extensive adhesions; in the other, slight but firm adhesions were found.

In cases under my care recently, quinine has been administered in large doses in the twenty-four hours preceding the operation, with a view to obviate shock, and in this respect its use has been attended with success. Thirty to sixty grains, in divided doses, have been given, and in each case so treated shock has been absent. In the preliminary and after-treatment it has also been given in tonic doses.

The duration of the operation has varied from thirty minutes to two hours; in the former time, mono-cystic non-adherent tumors have been removed and the wound closed. The latter period of time has been required to remove polycystic growths, with extensive and firm adhesions and many bleeding points to control. Serious complications during the operation and after-treatment have occurred in but two cases. In one already alluded to, the adhesions were so extensive as to complicate seriously the operation, and to render the result fatal. In the other, the slipping of the ligature and the persistence of hemorrhage for some hours after the closure of the wound complicated the operation. The patient's recovery was slow, two months and a half elapsing before she was able to leave her bed, in which period there occurred in order the following complications—obstinate, uncontrollable diarrhoea, supuration of hemorrhoids, formation of a large bed-sore over the region of the sacrum, with destruction of the sacro-coccygeal articulation and a condition of blood-poisoning with swelling of the left

parotid gland. Recovery finally took place, and the patient has been able to maintain herself by her work as a seamstress.

The size of the tumors varied greatly, and the weight from three to sixty pounds.

With one exception, all of the operations have been performed either in private houses or in a private hospital. One was operated upon in a private room of a general hospital, and in this a fatal result ensued—death, however, could not be attributed to this fact, but rather to the complications which existed in the case. In all cases careful attention was given to the preparation of the apartments, so that the patients should be placed under the most favorable hygienic conditions.

In the cases in which the progress was favorable, the patients, as a rule, sat up in bed on the twelfth day, and on the fourteenth were permitted to get out and occupy the lounge or an easy chair. At the end of the third week gentle exercise about the house, and in favorable weather in the open air, was allowed. This exercise was continued daily so as to prepare the patient, if living out of the city, for the journey home, which was undertaken between the fourth and fifth weeks after operation.

For twenty-four hours after the operation no food was given—at the end of this time, one ounce of milk, with lime-water, if vomiting had occurred or if there was nausea, was given every three or four hours. In two or three days the amount of milk was increased to two ounces every three hours, alternating with a teaspoonful of beef-juice in three tablespoonfuls of water. In some cases the beef-juice was administered instead of the milk from the first. As convalescence advanced additions were made cautiously to the diet, no solid food being given until the sutures and clamp had been removed, and the bowels moved freely by enemata.

Usually enemata of soap, water and olive oil were administered on the eighth day, and on alternate days subsequently, until evacuations occurred naturally. The catheter was used every six or eight hours for five days, and then efforts at evacuation of the bladder were permitted to be made by the patient.

When possible to avoid it, opiates were not administered. When required to relieve pain or secure rest, morphia in one-sixth to one-quarter of a grain was given hypodermically.

In the twenty-five abdominal sections death occurred in four cases—three after operation for the removal of ovarian cysts, and one after operation for the removal of the child in extra-uterine foetation. Septicemia was the cause of death in two of the ovarian operations, and in the case of extra-uterine pregnancy. Shock and hemorrhage produced a fatal termination in the case of malignant disease of both ovaries in which double ovariectomy was performed.

—Cockroaches, says a correspondent of *Land and Water*, who has lived with them in all the five quarters of the globe, will not touch bookbinding varnish with a mixture of 1 part copal varnish and 2 parts oil of turpentine. With a large brush paint this over the cloth binding, and let the book stand to dry. Unfortunately, it cannot be applied to the edges.

EDITORIAL DEPARTMENT.

PERISCOPE.

Antiseptics.

In the *New York Medical Journal*, Dr. Willard Parker, speaking of carbolic acid in the treatment of wounds, says he singles it out for the reason that it is better known by the profession, and more closely bound up, so to speak, with what we know as Listerism, than the other drugs that are used for like purposes. It is his decided conviction that the use of carbolic acid is a valuable adjuvant in surgical practice. As a mere disinfectant, it is perhaps in no way superior to a number of other agents; probably inferior to some. But as an antiseptic and detergent, it is not surpassed by any other substance. Its efficiency in averting inflammatory complications is mainly due to its germicidal properties. It is valuable also as a topical stimulant to ill-conditioned suppurating surfaces, such as the walls of cold abscesses and the like. It is especially needed when wounds have to be dressed in a vitiated atmosphere.

Dr. Robert F. Weir, after an individual experience of nearly six years in the wards of the Roosevelt, New York, and Bellevue Hospitals, depends in the main on carbolic acid as a germicide. Yet it has the disadvantage of occasionally acting toxically on patients. Next to carbolic acid, he regards iodoform and bichloride of mercury as the most secure germicides. He uses iodoform by insufflation upon the wounds, also iodoformized gauze, which is made by impregnating the gauze, previously washed with 50 parts iodoform, 250 parts ether, and 750 parts alcohol. This gives a ten per cent. gauze. In the employment of bichloride of mercury as an antiseptic, about six grains to the pint are used, or a solution of similar strength is irrigated over the wound. Sponges and compresses are also used in this solution. Gauze also is dipped in a solution of forty grains of corrosive sublimate to a pint of alcohol, to which is added one and a half ounces of glycerine. Under such dressings, within a short time, an amputation at the hip joint has passed satisfactorily towards complete recovery. The additional advantages of the sublimate dressing are its freedom from odor, its slight effect upon the hands, its cheapness and easy preparation. With these three antiseptics all wounds under his care are now being treated, preference being given to carbolic acid. Volkmann reiterates his remark, that no suppuration will take place if septic infection is prevented. Esmarch and Nussbaum pronounce a surgeon criminal in neglecting antiseptic measures.

Dr. William Bull, surgeon to St. Luke's and to Chambers Street Hospitals, London, does not think the antiseptic treatment generally enough adopted by practitioners as desirable. It is admitted to be indispensable for all important operations and wounds, and in wards where many patients are congregated, but is thought unnecessary or of less value in the minor wounds which occur in every-

day practice. Now it is a fact that these minor wounds may be the starting-point of the most serious inflammations, and it is hence most important so to treat them as to prevent such inflammations. It is to wounds of the scalp and hands, and small wounds in the vicinity of larger joints or overlying the pleural or peritoneal cavity, that he directs its use.

Removal of a Colossal Tumor.

Dr. Bruntzel, of Breslau, has successfully removed the left kidney, with a colossal fibroma of its capsule. The fact is worth recording as another triumph of abdominal surgery, for the growth weighed thirty-seven pounds and a quarter. The patient was a female, thirty-three years of age. The tumor was first noticed five years before, and had gradually increased in size; it was painless. When seen by Spiegelberg and Bruntzel in 1879, it was thought to be probably connected with the uterus; menstruation was natural, and had been so since the age of fourteen. An exploratory puncture revealed nothing. In June, 1882, there was much emaciation, but no genuine cachexia; the swelling reached from the ensiform cartilage to the pubic symphysis, and distended the abdomen uniformly in all directions; there were no physical signs of disease in any other organ. Abdominal section was performed in July, with strict antiseptic precautions; the incision extended from the xiphoid process to the symphysis pubis. The tumor was found to be retro-peritoneal in situation. The descending colon was felt in front of it at a hand's breadth from the mesial line. Punctures were made into the fluctuating growth without success, but by perseverance the enormous tumor and kidney were got out; the vascular pedicle was secured, the wound closed and drained in the manner of an ovariectomy, and compression and orthodox Listerism were adopted as dressings. There were marked signs of collapse on the removal of the fibroma, which were combated by hypodermic injections of ether and the performance of artificial respiration. The tumor was found to be a gigantic fibroma, which had originated in the left renal capsule, and was composed of a number of lobes, of sizes varying from a child's to a man's head. In this dense fibrous structure there were some areas of a loose, fatty nature, and in the centre was a reddish-yellow area of softening, with a thrombosed vessel in its neighborhood. The left kidney was seated in a hilus, and its structure was quite normal. The sensation of fluctuation that had been felt was probably due to the presence of the intermingled fat. The operation lasted two hours and a half. After the operation the pulse was very frequent, the temperature varied a little, the belly remained quite flaccid, and the discharge sweet. Vomiting never occurred, but some discomfort was felt from the loaded state of the tongue and mouth. The quantity of urine was very small for the first six days,

but after that it attained to the normal, and so remained. A loose stool was passed on the eighth day. The superficial sutures were removed on the seventh day. The drainage-tube was done away with on the ninth day. On the tenth day something sudden happened, for the temperature rose, and the patient became unconscious and collapsed. This accident was attributed with justice to the descending colon having been ulcerated through, and the escape of a little feces from the small sinus yet remaining. The fistula healed, after being cauterized, in the beginning of August. A fresh escape of feces began at the end of the same month, and, although very small in amount, lasted. Another accident of a very interesting nature happened immediately after the operation, namely, paralysis of both *upper* extremities. Bruntzel speculates on this being a reflex mechanism. It lasted in the right hand almost six weeks, and longer in the left. For treatment faradization was used. We should like to know more of the distribution and electrical reaction of this paralysis. Notwithstanding these unfortunate occurrences, the patient did so well as to get up at the fourth week, and her weight was seventy-five pounds (just as much again as the tumor weighed). Further improvement of the general health took place, but menstruation had not returned.

Perisplenic Abscesses.

The *Medical Times and Gazette*, December 16, 1882, says that M. C. Zuber (*Revue de Médecine*, November, 1882, No. 11) has written a thoughtful and suggestive essay on this subject, based on an attentive study of two patients who had come under his own observation. Both were adults; both had been exposed to malarious influences; in neither was the condition suspected during life; in both the spleen was found to be normal as regards its substance, though there were in each case patches of thickening in the capsule. He gives a brief abstract of some dozen cases which he has been able to find recorded, and then discusses their causes and mode of origin, summing up his results much as follows: 1. In the upper part of the abdomen we meet with purulent collections which are called perisplenic, though they may only touch the spleen at one point of its surface, and are by no means confined to a subserous cellular area around the spleen; by preference they occupy an irregular space bounded by the stomach, spleen, colon, and diaphragm. These collections are the termination of a circumscribed peritonitis, usually due to lesions of the spleen or alimentary canal. The infectious inflammations of the spleen (including thereby the effects of malaria) and the circular ulcer of the stomach, play the principal part in the production of these intra-abdominal abscesses. 2. Purulent collections arising in connexion with the alimentary canal contain air, and this admixture betrays itself by a group of symptoms remarkably constant, which may be summed up as a more or less complete resemblance to pyo-pneumothorax, the more so when they are only separated from the pleura by the much-arched diaphragm. The nature of this false pneumothorax will be recognized at first by the existence of grave symptoms referable to the alimentary canal; later on by the

variability, the exaggeration, or the insufficiency of the physical signs observed. Collections which take their origin from the spleen have hardly any characters beyond the tumefaction and pain in the hypochondrium; and the general signs of latent suppuration—tumors more or less marked or fluctuating—are rare. The diagnosis almost entirely rests on the process of exclusion. 3. Whatever may be the origin, depth, or extent of these perisplenic collections, they are not beyond the resources of modern surgery. This, then, is the essential practical point: we must spare no effort to arrive at determining, first, the existence, and next, the nature of these abscesses, and not be unnecessarily timid about making deep and repeated punctures. Performed methodically and with prudence, such explorations make our patient incur but little risk (recent works on abscess of the liver afford ample proof of this); and, on the other hand, they alone can form the starting-point of a truly rational and useful mode of treatment.

A Somewhat Unique Case of Opium Addiction.

Dr. J. B. Mattison, of Brooklyn, N. Y., writes: "It is now nearly ten years since we began giving attention to the study and treatment of opium addiction. In all cases coming under our care, and they number not a few, there has not been an exception, save a single instance, to our assertion made some years ago in this and other journals, that the vast majority of opium *habituated* become such *not* from choice, not from merely vicious indulgence—an idea mistakenly held by many both in and out of the profession—but from a *physical necessity*, having, ordinarily, its genesis in some painful ailment demanding the use of opium, which, when its legitimate need was fulfilled, had forged around its unsuspecting victim a chain so powerful that self, unaided, was powerless to break it. Of this fact, to our mind, there is no question, for among those under observation have been men from various walks of professional life, mainly, much as it may cause surprise, from our own fraternity: men ordinarily of iron will; men who have faced death upon battle-field and in prison-pen; men of strong mental parts, notably among them one filling a leading seat in the higher council-hall of the nation, whose brilliant intellectual accomplishments surpassed those of any public man whose acquaintance we have had the honor to enjoy; and the personal testimony supported by the clinical history of them all has proven beyond dispute that their opium-taking was an *absolute necessity*, before which the will resistlessly went down. We well know that many maintain an opposite opinion, and are disposed to extend censure rather than charity to these unfortunates; but we have no hesitation in expressing the profound conviction, based upon years of observation, that this is a most mistaken view of the subject, and that opium *habituated*, as a class, instead of being maligned and misrepresented, as so often is done, deserve commiseration and the same measure of sympathy as we would desire had this 'horror of deep darkness' fallen on us. The exceptional case to which allusion has been made, came under my care during the past year, and presents a factor in its etiology somewhat unique,

and of special interest to any professional gentleman whose zeal in the pursuit of therapeutical knowledge may tend to outrun his discretion. Dr. A. B—, was attacked by facial neuralgia, so severe as to compel his taking one-quarter of a grain of morphia hypodermically, at bedtime, to secure ease and sleep. This amount was increased to one-half a grain per diem during the following month, when, the neurotic disorder having subsided, the opiate was abandoned with little or no inconvenience. Some time after this, a gentleman addicted to the use of morphia placed himself under his care. Then Dr. B—, as he asserts, without the least desire for opium, but solely from a wish to discover, if possible, some antidotal drug to aid him in the cure of his patient, began experimenting on himself with hypodermic morphia, with the result of falling a victim to its seductive influence; and yet, though he failed to make the wished-for discovery, managed the case of his patient so well that success crowned his effort, while he, despite every endeavor, was unable to extricate himself from the pit into which he had unwittingly fallen, and was obliged to seek aid for his relief. The moral of this story is obvious. Experimenting on one's self with morphia, especially hypodermically, is dangerous; and if any of our readers are thus tampering with the drug, the best advice we can offer is, *quit*. It may be of interest to note, in closing, that Dr. B— made a very gratifying recovery, leaving for home at the expiration of seventeen days—had circumstances demanded, he could have done so a week earlier—and later tidings reported him doing well."

Carcinoma of Breast.

The *Medical Times and Gazette*, Dec. 16, 1882, says that Dr. Otto Sprengel has collected all the cases of cancer of the breast treated in Volkmann's clinic from 1874 to 1878—altogether 131 cases. We collect the principal conclusions from an abstract in the *Deutsche Med. Zeit.*, No. 42. Three etiological questions were inquired into:—(1) Marriage: A great number of children appear to exercise an unfavorable influence, as does also irregular lactation (four women were able only to nurse on one side; carcinoma developed later on in the other breast). Puerperal inflammation showed itself as the most frequent cause. (2) Traumatism: No certain information was made out in this direction, but the possibility must generally be granted, that, in consequence of long-continued irritation, carcinoma of the breast may develop. (3) Heredity was traced only thirteen times out of 109 cases. Sprengel does not believe in a cancerous cachexia, because the general condition of the patients was not bad (except, we presume, the fatal cases). It is a matter of common remark how well and hearty carcinoma of the breast, in the early stage, finds its victims. Carcinoma was as frequent in the left mamma as in the right. Growth more frequently invades the skin than the muscles, and affection of the skin was found to be especially associated with enlargement of the axillary glands. The development of secondary growths (metastasis) may be expected in about two years. The treatment in cases suitable for operation is extirpation only. In other cases, scraping, the

actual cautery, dressing with tannin, and compression with wadding, are the best modes of treatment. There were ten deaths in about 200 (including cases of recurrence) operations. In fifty-four cases recurrence took place, on the average in eight to six months, most frequently in the course of the first six months. Recurrences were dependent on extension of the disease, and happened most frequently in the axilla; hence the necessity of clearing out disease thoroughly from this space. Fifteen times out of 131 cases there was no relapse after the expiration of three years, and these were regarded as cured. In other cases, in which the wound did not heal, no doubt life was prolonged. Finally, the author advises operation at the earliest possible date. It will thus be seen that the result of statistics made in Germany is quite in accordance with the practice of most British surgeons—early and complete removal of the whole of the diseased breast, and of the lymphatics, disease of which, as Professor Lister remarked at the last meeting, but one, of the Clinical Society, is as much a local disease as the tumor.

The Distribution and Germ Origin of Cancer.

Dr. R. S. Gutteridge writes on this subject to the *Lancet*, December 2, 1882: In the year 1875 attention was afresh directed to the geographical distribution of disease by the lectures of Haveland. Turning to one of the maps by which they were illustrated, that on cancer, we find that each bank of the Tweed about Berwick, of the Tyne at Newcastle, of the Swale, the Ouse, and the Humber in Yorkshire, the Trent about Nottingham, and the whole of our beautiful lake districts, are most fertile beds of cancer. Wales is nearly free except about the Conway and the Dovey; so are the manufacturing districts; whilst Chester, Shrewsbury, Derby, Newark, and Lincoln are bad, as are also parts of Birmingham, the towns of Nuneaton and Lutterworth, and Huntingdonshire, Norwich, Stamford, and Peterborough. Cornwall is comparatively free, except in the neighborhoods of Falmouth and Bodmin. A belt of liability runs across Devonshire from Barnstaple to Exeter and Exmouth. Plymouth and the vicinity, with Totnes, is above the average; as also are Taunton, Axminster, and Bridport, Wells, Warminster, Blandford, and Poole in Dorsetshire. Bath stands high for mortality from cancer; so do Tetbury, Marlborough, Devizes, Shaftesbury, and Lymington. The Isle of Wight is all but free from cancer; and so is likewise the New Forest. Brighton and its district are bad; so are Hastings, Romney, Marsh, Folkestone, Dover, Deal, Ramsgate, and Margate. Coming nearer to the metropolis, we find that in Chertsey, Guildford, Dorking, Epsom, Reigate, and East Grinstead cancer is pretty equally prevalent. The huge London district, with the exception of Uxbridge and Hendon, if we extend it to Oxford and Aylesbury, with St. Albans on the one side, to Ware, Epping, Ongar, and Shoeburyness on the other, constitutes one appalling cancer field. In London proper, strangely enough, the parish of St. Luke's, the swarming neighborhood of Bishopsgate, crowded Bethnal Green, far away Old Ford, Bow, Poplar, the Isle of Dogs, savory Rotherhithe, and fragrant Bermondsey, are almost entirely exempt.

The west, the north, the south as far as Wandsworth and Clapham, have a second degree of mortality; the parts about the Marylebone-road, Regent's-park, and Primrose-hill are exceptionally bad. The returns for London go to show what is demonstrable in another way—that density of population, hard living, and laborious toil, have very little to do in favoring the appearance and growth of cancer. Liverpool, like London, is situated on the banks of a large tidal river; it has a teeming and not over-sober population; its deaths in 1878 from all causes, out-numbered by a thousand the total of its births; and yet it, with this heavy general mortality, has an enviably small percentage of deaths from cancer; the reason being that it is surrounded by a district not liable to cancer—one, in fact, affording the lowest mortality from this cause. On the contrary, London is a huge cancer-bed in itself, and at every conceivable point the country for many miles round is almost equally bad. From these facts Haviland deduces the following conclusions: All places and districts with a high mortality from cancer present common characteristics. They have rivers or streams taking their rise in soft, crumbling rocks; the volume of water is liable to overflow after violent rains or sudden thaws, submerging the country to a greater or less extent on either side. The subsidence of these floods is very much more gradual than the rapidity with which they spread. Hence a complete saturation of the soil to a considerable depth, and from the surface a constant exhalation of decaying vegetable and organic matter. The land having never time to purge itself from the poisonous malaria thus engendered, has a store constantly in hand with which to welcome the next deadly overflow. Hence, I would submit, that it follows incontestably that cancer beds, once formed in this fashion, must go on in an ever-increasing ratio in the manufacture, propagation, and dissemination of germs which are the sole efficient cause of cancer.

If this theory, which I contend the logic of facts establishes, be correct, it throws much light on the increase of cancer, its apparent hereditary nature, its liability to return, and preponderating influence amongst females, whilst it affords some hope of successful treatment.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—Two English diaries, the “Chemist’s and Druggist’s Diary,” and the “Sanitary and Medical Records Diary,” are publications of convenient office use, and contain a quantity of interesting tables and memoranda.

—The genesis of tumors has lately been the subject of close study in the laboratory of the University of Pennsylvania. Dr. H. F. Formad maintains the proposition that all primary tumors are direct products of the inflammatory process.

Dr. Henry Wile has made many experiments in relation to the pathogenesis of secondary tumors, resulting in establishing the fact that metastatic malignant tumors develop in exactly the same manner as particles of normal tissue. The reprints setting forth these results may be obtained of the authors.

—Dr. Edward Borch, of St. Louis (1225 Washington avenue), will send any of the following reprints of his various articles to those interested in the subjects: “Fracture of the Femur” (with cuts), “Ovarian Tumors,” “Reflections upon the History and Progress of Wounds and Inflammations,” “Simple Methods to Staunch Accidental Hemorrhage” (with cuts), “Observation on Surgery in Children,” “Compound Dislocation of the Wrist” (with cuts).

—In a reprint from the “Medico-Chirurgical Transactions,” vol. lxx., Mr. Reginald Harrison describes an interesting case of lithotomy, where a tumor of the prostate was successfully enucleated.

—The Biennial Report of the Alabama Insane Hospital, Dr. P. Bryce, Superintendent, has some points of interest. Out of 1835 patients the alleged exciting causes of insanity were: Religious excitement, 91; masturbation, 42; and the use of tobacco is charged with 25 cases. One interesting point of discipline is mentioned which deserves to be brought to general notice. The Superintendent writes:

Speaking of the value of a proper discipline of the nurses and employees about an establishment of this kind, I would state that the system established here twenty years ago, of imposing a small fine in money for every careless or wilful neglect of duty, is still in vigorous operation. This system, so far as I know, is peculiar to this hospital; and besides effecting a saving to the institution in money, it enforces an attention to duty which I am satisfied no other method can so easily and pleasantly effect. It serves, too, I am further convinced, to secure us a more reliable and efficient corps of nurses and employees, since the insubordinate and worthless characters, who are always on the lookout for easy places, seldom apply to us for employment.

—A new Homœopathic Pharmacopœia, published by Boericke & Tafel, of this city, has been suppressed under the copyright laws, and the entire edition destroyed. About 1,500 copies were printed, and the publishers will lose \$2,500 on the venture. A large portion of the book, it is alleged, was copied from the United States and National Dispensatories. It is open to question how far scientific facts should be considered controlled by such laws.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year.	\$5.00
Quarterly Compendium of Med. Science, - - -	2.50
Reporter and Compendium, - - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

DISTRICT PHYSICIANS.

As a class, the medical profession is notoriously and culpably negligent of its temporal interests.

There are, of course, certain individuals among us who have the bump of money-making well developed, and who turn every move, every action, almost every word, into cash; but they do so only for themselves, individually, and seem perfectly indifferent concerning the pecuniary welfare of their brethren.

We have our associations, our societies, it is true, wherein doctor meets doctor; but they meet, not to devise plans for causing a more substantial recognition of the physician's services, but rather to compare experiences in the progress of our science.

This, it is true, is a much more æsthetic aim than is the pursuit of "filthy lucre," but it will not buy bread and butter and clothing.

The old-established practitioners seem to forget that they were once struggling, half-starving aspirants for the positions they now so greedily and persistently hold on to; and so forgetting, neglect to use their influence to remove from the paths of the young men of to-day the obstacles against which they repeatedly stumbled in the days of "Auld Lang Syne."

Possibly they consider that adversity is an excellent teacher, and that each obstacle met and surmounted without extraneous aid gives that much greater force of character and determination to the young man.

In this, to a great extent, they are right. The leaders of our profession to-day walked any but rosy paths thirty years ago, and they no doubt feel that much of their success is to be attributed to the very difficulties they have encountered.

But when we reflect for a minute, can we not each of us recall some instance where a bright and promising young man has been literally forced out of the profession, and his talents and years of labor lost to science, because it became absolutely necessary for him to make in some trade or business that livelihood which his profession failed to afford him.

We have had occasion more than once in these columns to advocate the establishment of certain positions suitable to be filled by medical men, such as Sanitary Inspectors, Police Surgeons, etc., which, if properly considered, would be recognized as absolutely essential to the higher form of collective human life, or to speak more plainly, of good government. The medical profession and the leaders of it, those whose age, reputation, and acquaintanceship give them influence with legislation, are the ones to take this matter in hand.

Organize and persistently labor, until you have succeeded in securing from the proper authorities the establishment of positions calculated to preserve the health and lives of the people, and then see to it that these positions are filled by worthy young men.

Force a liberal (but not extravagant) remuneration, so that the young physician may live on his salary, and give his labors to science, while waiting for private practice.

You, old men, are the ones to do this, and it is a duty you owe to your youthful confreres.

You have not fulfilled the measure of your obligations when you perform your duty to yourselves and to your patients; you must have a watchful care over the young men, preparing to carry on your grand and noble work when you leave off, when called to your reward; and you are as much bound, morally, to fulfill this duty, as is the bishop to look after the welfare of his clergymen.

We wish in an especial manner to speak about the remuneration of "district physicians" in this city. They are very hard worked as a class, visit many patients, do an immensity of good to the poor, and receive, we believe, one hundred and twenty dollars a year. The injustice of this remuneration will be apparent to any one who gives the matter a trifle of investigation; who notes what large areas are covered by the various "districts," and how many visits are made.

In the city of Washington, the city physicians (there are fourteen of them) receive each \$600 per year. So should it be here; this is a fair figure,

and would prove a godsend to many a worthy, ambitious, but poor young man.

You old wiseacres, take heed of what we say; scratch your gray heads, and evolve some charity therefrom for your young brethren; help them along—it won't hurt you *here*, and may help you *hereafter*.

RAG-SORTING AND SMALL-POX.

The recent outbreak of small-pox among rag-sorters in mills, points a hygienic moral that should not be neglected.

That the poisonous agency of contagious diseases may retain its activity for a long time is well known.

That the rags taken into the mills are collected from all sources and are not overly clean, is equally well known.

That epidemics (and violent ones) of small-pox have frequently arisen in this way, is also well recognized.

That they *ought* not to, is a fact exceedingly familiar to every sanitarian.

The remedy! We find it in two words; *vaccination*, *disinfection*. So much has been recently written about vaccination, that we will refrain from further infliction of our readers on the subject.

But for disinfection of these reeking, filthy rags, we must make a strong demand.

We should have legislation forcing manufacturers to thoroughly disinfect these rags before any human being is allowed to handle or assort them, and by so doing stir into the atmosphere the disease-germs lurking in them.

We cannot conceive of a greater source of disease than this, and we should compel our rich mill operators to give some thought to the health of those whose labor makes their wealth.

REPORT ALL YOUR VALUABLE CASES.

Within a few days, in conversation with a physician, he made the remark, "Dr. So-and-So has, to a great extent, made his exalted reputation because he fails to report his unsuccessful cases."

That this is true of the majority of physicians,

we will all admit, until the accusation is brought home to ourselves.

That it is wrong, and that it tends to hinder the upward progress of our science, is equally true:

We realize that it is against the instincts of nature and the doctrines of self-preservation for a man to acknowledge voluntarily his failures, and it would seem too Utopian to hope that such a consummation can ever be achieved; yet must it seem clear to every thinking man, that conclusions or statistics based upon such partial and one-sided reports can serve only to mislead those whom they are supposed to guide.

Can we not rise above this petty selfishness, and in our medical societies and our professional journals, admit our failures as well as our successes?

The *capable, intelligent physician never fails through his own fault*; his lack of success is invariably due to circumstances beyond human control.

Should such a man, then, report a failure, and explain, as far as possible, the causes that led to failure, and demonstrate the fact that every possible precaution to insure success was resorted to, he will receive from his *capable and intelligent* hearers, a universal commendation of his honest, manly, *scientific* course; while the professional snarlers will do him no more real injury than does the barking cur to the legs of the noble stallion.

Statistics will then be reliable, and we will have made a great step in our march to exactitude.

CAN THERE BE TRUE SPECIALISTS?

The question has been raised by a very prominent physician—an *old-timer*, a solid, substantial member of our profession, who, while an ardent admirer of progress, yet deprecates the present divisional system of medicine—whether there can be a *true specialist*, and he tells the following story:

A wealthy man was *sick*; he consulted his physician in this country; *kidney disease* was the verdict; he went to France; you have *heart disease*, said the Frenchman; he went to Germany; your *brain* is affected, was the conclusion of the German.

In each instance the gentleman consulted was a

so-called specialist on the disease with which he pronounced his patient afflicted. Finally, the man died, and it was found that all were right. The man had kidney disease, he had heart disease, and he had chronic congestion of the brain. But, said our story-teller, the kidney affection was the result of the heart affection, or the heart disease was the natural outcome of the kidney disease, and the brain trouble was the necessary consequence of imperfect action of both these important systems.

Therefore, he says, can a man really devote himself to any one special set of organs? He thinks not, and we agree with him,

The human body is too much of an entity for any one system to be exclusively deranged, while the others remain healthy.

Action and reaction are the two great rules of organic life; one diseased organ will react injuriously on a healthy organ, and so on throughout the whole human system.

Mechanically, we may have *specialists*; a certain man may have particular adeptness (acquired by constant practice) in examining and operating upon the eye or the ear, the nose or the throat; but then he verges on the province of surgery.

We fear and hope that specialism, carried to the extent it now is, will soon prove one of the *schisms* with which our profession has been, from time immemorial, afflicted, and will live its day, to give place again to the two regular and legitimate divisions, viz; *medicine and surgery*.

Surgery really is a special branch of medicine, and a justifiable one. When a physician recognizes the necessity for the *mechanical* treatment, he can and will recommend the surgeon; but for a man who realizes the interdependence of all the parts of the human body to advocate the special significance of any one single system, seems very impracticable, to say the least.

Asthma Cigarettes.

Impregnate well-nitred tobacco with an alcoholic fluid extract of grindelia; let dry and use in cigarettes. Owing to the nitre, they will continue to glow and to develop smoke. So says the *Boston Journal of Chemistry*.

NOTES AND COMMENTS.

Haematemesis Due to Visceral Syphilis.

A butcher, aet. 39, had become very anæmic in consequence of vomiting blood and loss of blood by the bowels. Dr. A. Hiller (*Monatschr. f. Prakt. Dermat.*, July, 1882), who attended the case, made the following diagnosis: There was a history of syphilitic infection, sixteen years ago; many characteristic and partly recent cicatrices were found on the gums, a characteristic ulcer on the septum of the nose; further, there was present a mild icterus, enlargement and sensitiveness of the liver, hypertrophy of the spleen without ascites, no fever, absence of any symptoms or signs denoting a gastric lesion; basing his opinion upon these, he came to the conclusion that it was a case of syphilitic disease of the liver, probably in the form of a syphilitic cicatricial constriction, and in consequence of the latter, an obstruction to the circulation of the portal system, but not of sufficient degree to cause watery effusion. The blood evidently came from peripheral branches of the portal vein in the stomach and the beginning of the small intestines, and probably caused immediately by bodily overstrain and overfilling of the stomach.

The patient was first placed upon styptics, and then an anti-syphilitic treatment instituted. The success of the latter was so remarkable that before the lapse of a month the patient had lost all symptoms and signs of his former malady, was strong, stout, and even plethoric, and felt so well that he could not be induced to await a perfect cure in the hospital, but left.

The Straight-Bodied Position in Labor.

In the *British Medical Journal* for December 2, 1882, Dr. A. Drummond McDonald appears in an article entitled "The Straight-bodied Position in Labor." He desires to corroborate an observation made by Dr. G. Hurt, of this country, that a sharply-flexed and abducted position of the thighs conduces to perineal injury, although he does not believe, with Dr. Hurt, that this position relaxes the perineum, but only that no artificial pressure is put upon it. "In every case where the presenting mass has almost reached the perineum," he says, "the patient should be placed in the straight-bodied position; that is, with the lower extremities adducted, and in the same straight line with the body. The effect of this position is to retain the natural obtuseness of the angle of inclination of the perineal plane; it straightens the vaginal parts of the passages and prevents the

sacral segment of the floor being converted into a valvular lid for the pelvic box in its coccygeo-pubic plane. Hence, a demonstrable source of speedier labor." He cites 18 cases—19 children, there being one twin labor. There were ten primiparae, three secundiparae and five multiparae. Eleven mothers were delivered by forceps. The results are as follows: Fourteen cases afforded positive proof in favor of the straight-bodied position; two gave negative proof in its favor, and two tended to prove that straight-body *plus* support exercises only a slight beneficial influence, where there is genuine rigidity of the perineum, though it is probable that the flexed thigh position *plus* support would have produced a worse result. He believes that the other methods for acceleration of delivery and prevention of laceration find a valuable adjunct in the straight-bodied, or, as he proposes to call it, the *orthoclematic position*.

Nephrectomy.

The operation of nephrectomy, so popular of late in New York, has not been resorted to as enthusiastically as it was before the recent removal of the kidney from a patient in one of the city hospitals. No urine was passed after the operation, and the woman died in two days. It was found that there had been but one kidney—that removed by the surgeon. It is unnecessary to offer any comments upon this case, as "he who runs may read."—*Medical News*, December 23, 1882.

Treatment of Croup.

In the classification of diphtheria and croup, Prof. Dujardin-Beaumetz considers them the same (*Medical Record*), and states that the medical methods of treatment should be the same. In entering on the description of croup, he says: "In France we are agreed that pseudo-membranous croup is the extension of diphtheria to the larynx, and we reject altogether the possibility of an inflammatory 'catarrhal' croup, a notion which has been supported in Germany."

In regard to the use of emetics, he seems to be inclined to the use of apomorphia; the dose in adults $\frac{1}{2}$ of a grain, for young subjects $\frac{1}{12}$, and for children of a still younger age $\frac{1}{30}$ of a grain, the medicine to be given hypodermically.

Mesenteric Cysts and Tumors.

Mr. T. Spencer Wells says, in the *British Medical Journal*, Dec. 9, 1882, that until last summer he had not met with any cases of mesenteric cysts or solid tumors. (In the *American Journal of Obstetrics*, Dec. 1882, a case of extirpation of

a cyst of the mesentery is reported. Werth, whose case it was, thinks that it was a mesenteric gland transformed into a cyst.)

In Mr. Wells' first case he did not attempt to remove the cyst, only removing the fluid contents. On June 20, 1882, he removed a solid tumor, whose origin was clearly in the cellular tissue, at the root of the mesentery proper, near the lumbar vertebrae. All its blood supply was derived from the mesenteric vessels.

The uterus and both ovaries were healthy.

Mr. Wells concludes thus: "The removal of a solid mesenteric tumor may still be regarded as a surgical curiosity."

Tracheotomy.

The article upon tracheotomy and its discussion in the Society for Medical Observation reported in the *Boston Medical and Surgical Journal*, is most interesting and instructive, and especially can be appreciated by those who have been called upon to perform the operation. Points of election are different, and each seems to have its advantages. Too much stress cannot be laid upon the importance of performing the operation early, before the patient is too exhausted to recover under favorable circumstances, and the proper use of stimulants afterward. There is great inclination on the part of friends and many physicians to postpone operating until the last moment, hoping it may not be necessary; in this way many lives are lost through best intention. Stimulants pushed to the maximum endurance are indicated, particularly when the patient has been at all asphyxiated. The use of anæsthetics seems to be dangerous, from the liability to spasm of the glottis; and asphyxia contraindicates them always. The plan of placing a moistened sponge on the anterior portion of the neck is a valuable suggestion, for the patient must naturally be weakened by the sweating that follows a prolonged stay in a thoroughly heated atmosphere. In spasmodic croup, or laryngismus stridulus, the use of a drop or two of nitrite of amyl, on a piece of cloth and inhaled, is highly extolled by Dr. Cornelius Kollock, of South Carolina.

Elementary Composition of Starch.

So far the original formula of starch ($C_6H_{10}O_5$) has generally been accepted as correct, but frequently been disputed. Näyell says that the composition of amylum was $C_{36}H_{62}O_{30}$; Tolleur and Pfeiffer are undecided between $C_{24}H_{40}O_{20}$ and $C_{24}H_{12}O_{21}$. Dr. F. Salomon has recently made the subject a special study (I. f. Prakt. Chemic. xxv,

p. 348), and basing his decision upon experiments, by which the starch was changed to glucose and this by polarization, then again by the specific gravity of the solution, he arrived at the conclusion, that the old formula $C_6H_{10}O_5$ was the only correct one, and the only one which by the aid of polarization could be proven to be invariably the same.

Idiopathic Spasm of the Glottis.

This affection has been first accurately described by Fleury. Dr. O. Berger now reports two cases of this kind which came under his charge. (*Neurol. Cbl.*, 1882-3.) One was the case of a lady, æt. 28, not hysterical. She for several years had occasionally, and while otherwise in perfect health, suddenly the sensation of tension in the upper part of the throat, and her tongue appeared swollen to her. One to two minutes later the organ was seized by violent rhythmic contractions, 50-60 in a minute. The tongue was thrown forcibly against the front teeth. Nowhere could anything abnormal be detected. Cure was established by the long-continued sojourn at Landeck (spring containing iron). In the second case, a man æt. 42, the tongue was thrown forcibly out of the mouth. This had happened several times daily for over two years. A tonic treatment was here also successful.

Dr. Berger describes besides a spasm of the cremaster muscle, a complaint which he had opportunity to observe in two men (one 44 and the other 56 years old). In both cases the spasm occurred on the left side, lasted 2-3 minutes, and recurred several times daily. In the one case a long course of Kissingen and Carlsbad water brought about remissions of several months duration. The second patient received decided benefit from the subcutaneous application of atropia and of galvanization (anode in the lumbar region over the spine, cathode over the scrotum).

Dislocation of Astragalus.

In *The British Medical Journal*, Dec. 2, 1882, Mr. W. Hunt reports a case of forward dislocation of the astragalus, which he succeeded in relieving, without the aid of an anæsthetic, by making extension on the foot, and counter-extension by the arms, and pressure on the dislocated bone. The result is the more gratifying when we remember that the reduction is difficult and often impossible, without previous division of the tendo Achillis. If all attempts fail, it brings up the vexed question as to the advisability of removing the bone, especially if torsion or version exist.

CORRESPONDENCE.

A Case in Practice, Presenting Some Peculiar Features.

ED. MED. AND SURG. REPORTER:—

I was called on the morning of June 13, 1882, to attend Mrs. Z. in her second confinement, her previous one having occurred in 1878, when a remarkably healthy child was born, who is still living. This time she was delivered of a child in the seventh month of her pregnancy. The child had the wrinkled, weazened appearance of children born at that time, weighed three pounds, and lived four weeks. After the placenta had been removed, and I was in the act of adjusting the bandage, I discovered that the abdomen had not sunk, as is usual, and therefore I made an examination to satisfy myself that there was not another child in the uterus, but found nothing.

On my return the next day—14th—I found the abdomen still distended, a temperature of 103° F, pulse 100, and respiration 27. For about six weeks previous to this time, she had had the severest rasping cough I ever observed, which she said came from her stomach, and for which expectorants did her no good. As an epidemic of typhoid fever was prevailing at the time—her husband having had it within the year—I diagnosed it to be an attack of that disease, and believed it had brought on the premature delivery. During the next nineteen days her evening temperature averaged $103\frac{1}{2}$; minimum, 103; maximum, 105; her morning temperature $101\frac{1}{4}$; minimum, 98 $\frac{1}{2}$; on the seventeenth day, after fifteen grains of quinine the previous evening, maximum $102\frac{1}{2}$, respiration 24. The lochia was normal in quantity and quality, and milk was secreted in the mammae. Some difficulty in urination, of which she complained the first week, had subsided. On the twentieth, twenty-first and twenty-second days her morning temperature was $98\frac{1}{2}^{\circ}$, $99\frac{1}{2}^{\circ}$ and $98\frac{1}{2}^{\circ}$ respectively, and I believed convalescence established. She rested better, and her cough, which had been incessant, had gradually decreased to a half-hour paroxysm every evening or night. She had had no diarrhoea, but the bowels were easily moved with castor oil; took nourishment, and the tongue was kept in fair condition by mild alteratives. Did not complain of abdominal tenderness either on light or deep pressure, except over the region of the liver, which could be felt beneath the ribs.

It now being three weeks since the onset, and all the symptoms having almost subsided—except one—we concluded that there could be no mistake in our diagnosis. The unrelieved symptom was tympanites; and as this had been the initiatory, so it was the constant and unintermittent one to the end. After the twenty-second day the fever again arose to daily exacerbations of 103, 104, and 105, and remissions of 101 to 102—the maximum occurring from one to four a. m., and the minimum about the same hours p. m.

It would often rise three degrees in three hours or less, and fall as rapidly, sometimes with profuse sweating. The pulse rose from 140 to 160, and the breathing to 45 to 55 per minute. Delirium supervened; the urine and feces were passed in the bed, and she gradually failed in strength, al-

though taking considerable aliment until the 12th of August, 1882, when she died, sixty days after confinement.

At the autopsy we found the heart and lungs in a normal condition. The liver was about double the ordinary size, but its substance was healthy; but it was adherent to the abdominal parietes and to everything bounding it, either by close adhesions or by fibrous bands from a quarter of an inch to an inch in length. The omentum was firmly adherent to the parietal and visceral peritoneum, and the bowels were glued together to the extent that nothing could be separated except by close dissection. Peyer's patches, while partaking of the general glutinative condition, gave no positive typhoid evidence. The uterus had undergone perfect involution, and all the pelvic viscera were in a normal condition.

The points of query in this case are:

1st. The severe cough without any thoracic trouble, it being almost without intermission day or night for six weeks before confinement, and gradually abating from that time until death.

2d. The rapid rise and fall of temperature, and at such uncommon hours.

3d. The extensive adhesions without pain or tenderness; and

4th. Suggestions are solicited as to the correct diagnosis of the case. J. A. KIMMEL, M. D.

Findlay, Ohio.

Aconite and Belladonna in Erysipelas.

ED. MED. AND SURG. REPORTER:—

In your issue of Nov. 25, 1882, the treatment of erysipelas was spoken of. I wish to say a few words in regard to the treatment of that disease. For the last three years I have been treating it with aconite and belladonna, and with much better results than with other methods of treatment, either locally or constitutionally. I have found it superior to iron and quinine, or any treatment that I have used or seen used. The inflammation will begin to subside in from twelve to twenty-four hours, patient will feel more comfortable, and will go on to a speedy recovery. I have used it in cases of all ages, running from fifteen months to fifty years, and with like results in all. I generally give one drop of tinct. aconite root, and two drops of fl. ex. belladonna every hour, according to age. I very often direct a mixture of acid carbol., tinct. iodine and glycerine to be used locally. This is unnecessary as to cure, but it adds to the comfort of the patient. I have also found belladonna a very useful drug in the treatment of various skin diseases. I very frequently combine the fl. ex. and liq. pot., arsenit., and cure cases that have resisted other treatment.

J. E. RIGG, M. D.,

Stoner, Pa.

Treatment of Diphtheria and Pseudo-Membranous Croup.

ED. MED. AND SURG. REPORTER:—

I would respectfully reply to the request of "W. I. H.," M. D., Ohio, and refer him to the MEDICAL AND SURGICAL REPORTER of March 24, 1877, p. 265, where he will find what may be safely considered the most satisfactory treatment of diphtheria and pseudo-membranous croup. In the use of the lime

inhalations, I would urge that the air of the chamber be kept constantly moderately saturated with the vapor, and when paroxysms incident to the disease threaten, the inhalations be taken as freely as possible. To secure the best results from their use the vapor should be allowed to generate under a blanket suspended over and surrounding the vessel containing the lime and water, and the patient given access to the vapor by admitting the head and shoulders under the canopy at one corner of the covering. The space occupied by the vessel containing the slaking lime should be as large as it can be conveniently made. Lime inhalations, thoroughly administered, are efficacious in soothing the patient. They will prolong life and rescue from death.

THOMAS HAY, M. D.

1127 Arch Street, Philadelphia.

Foreign Bodies Swallowed.

ED. MED. AND SURG. REPORTER:—

In your journal of the 16th of December an article on "Foreign Bodies Swallowed" reminds me of a large peach-pit that was swallowed by a stout young laborer. It had reached the colon at its attachment to the sacrum, lying horizontally; the bowel contracted below it as though tied with a thread; only the rough side of the stone the size of a pea could be reached by the finger. A dose of oil was directed. A week later the oil had not passed; the pressing down was terrible. He was placed on his back, knees elevated, the index finger oiled and pressed up so as to touch the stone. A probe-pointed bistoury passed flatwise on the finger through the opening, which could only be just reached. The cutting edge was then turned toward the spine, when the stone was immediately shot across the room, followed by a copious deluge. He went to work without an unpleasant symptom afterward.

In your journal of September 20, 1873, may be seen an account of 21 pins, crooked and straight, having passed a babe one year old in two days.

EDW. VANDERPOEL, M. D.

New York.

NEWS AND MISCELLANY.

Porro's Operation.

The patient on whom Dr. Clement Godson, of England, recently performed Porro's operation on account of contracted pelvis, has progressed steadily towards recovery, and but little doubt is now felt in her ultimate complete restoration. The child also is healthy and doing well.

Pasteur's Researches.

M. Pasteur has gone to the valley of the Rhone to investigate a disease among pigs which has recently been fatal to 20,000. The disease is called "le rouge des porcs," and M. Pasteur announces that he has discovered its cause to be a very minute organism, which, in point of size, resembles that of chicken cholera. It differs, however, in its physiological properties, since it has no action on fowls, but it is fatal to rabbits and pigs, especially to white pigs. M. Pasteur has convinced himself,

by experiments, that one attack affords protection against another; and he has succeeded in inoculating pigs with organisms which have been weakened by culture, and in thus rendering these animals insusceptible.

Doctors of Medical Science.

The French Minister of Public Instruction has recently issued a circular to the doctors of the medical faculties and schools, requesting them to seek the advice of their various councils as to whether it would be desirable to create a new degree superior to that of Doctor of Medicine, to be termed *Docteur des Sciences Médicales*. While leaving the discussion on the subject free and open to the profession and academic councils, and desiring their opinion on the matter, the Minister observes that there are three points to be especially considered: 1. The utility of having above the doctorate of medicine, which is especially a professional degree, a superior degree indicating more complete and more scientific acquisitions, and more personal and more original studies. 2. What exigencies should be imposed on the candidates for the new doctorate beyond those already required for the doctorate of medicine? 3. In what way are the tests of the qualifications of the candidates to be settled?

Female Doctors.

An Austrian lady, who has graduated as a doctor of medicine at Zürich, has been refused permission to practice by the Cultus Minister of Austria. He holds that the diplomas of foreign universities can only confer rights on those who would be eligible for degrees at Austrian universities; and as these do not admit women as students, his decision debars all women, however well qualified, from all those professions for which a university degree is required. It is expected an appeal will be made to the law courts.

Competitive Examination in China.

An exchange says—"The yearly provincial examinations were held this autumn in Hongchow, the streets of which city are described as having literally swarmed with students of every age, from fifteen to eighty, and of all conditions, from the poor bank drudge to the sleek millionaire. The examination 'hall' was an enclosure of some eight acres, containing 10,000 cells for the students, each cell being about three feet wide, five feet deep, and seven feet high, and furnished with two boards—one for seat and bed, the other for desk and table. The candidates went in on the 8th day of the 8th moon, and remained in till the 10th—two nights and one day. They then came out, and returned on the 11th, when they went through precisely the same ordeal, which was repeated on the 14th, and they finally left their cells on the 16th. It is no unusual thing, we are told, for a candidate to be found dead in his cell."

A Centenarian.

From *The Lancet* we learn that Miss Sarah Apter, residing at Fern Villa, Garlands-road, Redhill, attained on the 29th of November the great age of 100 years, she having been born at

Reigate, on December 2, 1782. There is no doubt about the authenticity of her age, as the entry of her birth and the date may be found in the books of Reigate parish church. She enjoys very fair health, gets up and dresses herself every day, has a good appetite, and occasionally takes and enjoys a glass of port. She has only one useful eye, having lost the other, as she says, "from inflammation, in the month," meaning in the first month of her life.

Measles in Ohio.

A Georgetown correspondent writes that measles are prevailing in the vicinity of Georgetown, Ohio, as an epidemic, but as yet few deaths have occurred, although it is measles in town, measles around town, measles in the adjoining towns, and all you can hear is measles, measles, measles.

The Volta Prize.

We learn from the *Electrician* that a prize of 50,000 francs offered by the French Government, will be awarded in 1887 to the author of the discovery which shall be adjudged to have best increased the facility of applying electricity as the source of light, heat, power, chemical action, or as a transmitter of messages, or in the treatment of diseases. June 30th, 1887, is the last day for receiving claims, and the prize is open to scientists of all nations.

Solidified Tea.

From the *Scientific American* we learn the following process. One hundred grammes of ground sugar and 10 grammes starch sugar are boiled with the quantity of water required for solution, until the mass becomes tenacious, but yet remains transparent. After cooling, 50 grammes of tea, previously mixed with 50 grammes of dry sugar, are added. The plastic mass is pressed into moulds, and when solidified forms the preserved tea.

Domesticity as a Cause of Insanity.

The following, which we take from the *Boston Journal of Chemistry*, will afford food for much reflection. "Mrs. M——, aged forty-four, mother of eight children, acute mania. The husband, when asked if he could suggest any cause for her illness, exclaimed, with much animation, that he could not conceive any reason. 'She is a most domestic woman; is always doing something for her children; is *always* at work for us all; *never* goes out of the house, even to church on Sunday; never goes gadding about at the neighbors' houses, or talking from one to another; has been one of the best of wives and mothers, and was *always* at home.' " The superintendent, in commenting on this case, says, "This appreciative husband could hardly have furnished a more graphic delineation of the causes of his wife's insanity, had he understood them never so thoroughly."

Women Doctors in Spain.

La Tribuna, of Madrid, has a long account of the granting by the medical faculty of that city of a degree of medicine on Señorita Martina Casells y Bellaspi. She is the first Spanish woman who

has ever studied medicine and taken her degree. The paper speaks in warm terms of her as a lady who, in spite of much opposition and national prejudice, has won high honors. Another Spanish lady is following in Señorita Casells' footsteps. Finding the Valencian School of Medicine had closed its doors against her, she is now studying in Madrid, where she has met with a more friendly reception.

Chest Development by Exercise.

Dr. Cathcart, Lecturer on Anatomy in the Edinburgh School of Medicine, in a lecture delivered at the Edinburgh Health Society a short time since, gave, as to the effects of exercise in expanding the chest, some striking facts which related to a school where physical exercises had been systematically carried out. The effect of regular exercise was shown as follows: New boys, aged fourteen, average chest measurement, 29·3; at fifteen, 30·16; at sixteen, 32·0; at seventeen, 32·6; and at eighteen, 32·5; while former boys measured respectively 30·6, 32·1, 34·2, 35·8, and 36·8.

To Hasten the Action of Quinine.

Dr. Starke, in *Berliner Klin. Wochenschrift*, advises that before swallowing powder or pills of quinine, a weak tartaric acid lemonade be taken. This procedure not only greatly accelerates the solution and absorption of the quinine, rendering its physiological action much more prompt, but also obviates that unpleasant gastric irritation so common after the administration of large doses of this drug.

Hydrophobic Meat.

At Reading, Pa., lately, the authorities arrested two country butchers, charged with selling the meat of three hogs which were bitten by mad dogs and died of rabies. It is alleged that a number of persons became sick after eating the pork. Similar instances have been reported where the flesh of sheep bitten by rabid dogs have brought on severe symptoms. All such animals should be slain and buried or burned.

Professor Bergmann.

The Berlin correspondent of the *Medical Record* furnishes the following pen-picture of the successor to Prof. Von Langenbeck: Prof. Bergmann, of Würzburg, is a middle-aged man of forty-five (he was born December 14, 1836), and is the son-in-law of the well-known Russian State Councillor, Dr. Adelmann, of St. Petersburg. Only a few weeks since he was distinguished by the appointment as Surgeon-General à la suite, in the German army, and, together with Gerhard and Kölliker, forms the principal attraction of the Würzburg Medical Faculty. After the completion of his medical studies, he connected himself with the Russo-Prussian University at Dorpat, where he was at first adjunct, and later regular professor of surgery.

In the surgical world, Von Bergmann has become known through his exact and interesting studies of the septic properties of wound-secrections, and his experimental investigations into the pressure-symptoms sequent upon injuries of the

cranium. Further, he has published studies on different operative procedures and their technical improvement—the result, in part, of his experience on the field during the Franco-German war. In his practice, he is a firm advocate of Listerism. In the year 1871, he received a call to Königsberg as regular professor of surgery, and was preparing to accept the position when Dr. Schönborn was elected in his stead.

But in 1875, on the death of Professor Von Linhart, of Würzburg, Von Bergmann was appointed as his successor, and since that time he has occupied the chair of surgery, and has been director of the surgical division of the old and famous Julius Hospital in that town.

Treatment of the Wounded in Egypt.

During the recent war in Egypt the antiseptics used on the wounds were iodoform, and a solution of chloride of zinc, forty grains to the ounce. Sometimes one part of this zinc solution was added to three parts of in twenty carbolic acid solution, with excellent results.

Hunt's Satire.

In the course of his recent interesting address on Esmarch's criticism of the Garfield case, Dr. Hunt read E.'s criticism that "no antiseptic precautions were used to purify his hands by the physician who arrived first at the depot, before introducing his fingers into the wound." Dr. H. then said, "I would like to inform the distinguished professor that it is not customary in American railway stations to keep 40 per cent. solutions of carbolic acid on draught for such emergencies." The whole address was pointed and made doubly interesting by brilliant paragraphs of wit and satire.

A Good Thing in Vaccination.

The *Scientific American*, November 18th, 1882, is authority for the statement that the New York express train on the Erie railroad, passing eastward, was held at Elmira, November 9th, till physicians could vaccinate all the passengers not already protected. The cause was that a passenger afflicted with symptoms of smallpox was taken from the train at Hornellsville.

St. Louis Obstetrical and Gynecological Society.

At the annual meeting of the St. Louis Obstetrical and Gynecological Society, held November 16th, the following officers were elected for the ensuing year:

T. L. Papin, President; W. H. Ford, Vice-President; Walter Coles, Recording Secretary; M. Yarnall, Corresponding Secretary; T. F. Prewitt, Treasurer.

State and National Boards of Health.

The ill feeling that has always existed between the Board of Health of Louisiana and the National Board of Health has not diminished, to judge from a circular recently issued by the former. This document closes with these words:

"Whilst the National Board of Health was conducting an expensive system of detection and

espionage during a period of perfect freedom from yellow fever within the bounds of Louisiana, against her legally constituted Board of Health, pestilence had invaded Brownsville on the west and Pensacola on the east. The opinion was expressed that the members and employees of the National Board of Health could find a better field for the exertion of their energies and for the execution of the will of the representatives of the American people, in combatting pestilence and in assisting the plague-stricken citizens of Texas and Florida, than in expending the public funds and moneys exacted from the railroad companies, in the conduct of a so-called inspection service in the healthy city of New Orleans."

Such a feeling of opposition is, we believe; unnecessary, and should not exist between two bodies each deeply concerned in beneficent work. We cannot enter into the mutual grounds of complaint in this case, but we believe that it is possible and desirable to have both National and State Boards of Health, and that they could and should work in harmony.

A Dangerous Charlatan.

The Illinois authorities have notified the profession of a man who pretends to be a physician, and who shows a diploma issued to H. A. Luders by the University of Göttingen in 1866. The diploma is genuine, but the notice sent us states that the Illinois authorities have evidence that it is a case of personation, the real Dr. Luders having died in 1878.

The Prevention of Blindness.

We have received a circular containing the following facts from Dr. Haltenhof, of Geneva, Switzerland (to whom manuscripts and letters desiring further particulars should be addressed):

The Fifth International Congress of Hygiene, which will meet at The Hague, Holland, in 1884, will award the prize of two thousand francs (£80 sterling) offered by the London Society for the Prevention of Blindness to the author of the best essay written in English, French, German, or Italian, on "The Causes of Blindness and the Practical Means for Preventing It." Besides this prize, the International Society for the Improvement of the Condition of the Blind reserves to itself the right to award a second prize of one thousand francs (£40 sterling), or two prizes of five hundred francs (£20 sterling) each, and a silver gilt medal with a diploma, should it see fit, to such of the essays as should, in the opinion of the international jury for the principal prize, be deserving of it; the last-mentioned prizes will be distributed at the centenary festival of the first blind institution founded by Haüy, which will take place in Paris in 1884.

The Fourth International Congress of Hygiene, which met at Geneva in September, 1882, has adopted for this competition the following programme, as prepared by the London Society for the Prevention of Blindness:

I. THE STUDY OF THE CAUSES OF BLINDNESS:

a. Hereditary causes. Diseases of parents, consanguineous intermarriages.

b. Infantile eye diseases. Various inflammations of the eyes.

c. School period and time of apprenticeship. Progressive shortsightedness, etc.

d. General Diseases. Diatheses, various fevers, chronic poisoning, etc.

e. Trade Influences. Wounds and accidents, etc., sympathetic ophthalmia.

f. Social and climacteric influences, contagious ophthalmias, unhealthy habitations, defective lighting, etc.

g. Neglect of treatment and bad treatment of eye affections.

II. THE STUDY OF PRACTICAL PREVENTIVE MEANS.

a. Legislative means.

b. Hygienic and professional means.

c. Educational means.

d. Medical and philanthropic means.

Items.

—Dr. Flaminio Tassi, of Siena, has published a report of four cases of erysipelas, which rapidly yielded to a saturated aqueous solution of picric acid, applied morning and evening with a camel-hair brush.

—The *Union Médicale* reports the case of a woman who was delivered of three girls and a boy. The four children together weighed six kilograms and a quarter. Three were born dead and the fourth was very feeble.

—Dr. John Burdon-Sanderson, F. R. C. P. Lond., F. R. S., Jodrell Professor of Physiology in University College, London, has been elected Waynflete Professor of Physiology in the University of Oxford.

—The Municipal Laboratory, in Paris, for the analysis of the solid and liquid food sold in Paris, is issuing a series of reports, from which it is seen that, in fact, nearly every article of consumption is more or less adulterated. Coffee and chocolate are rarely sold pure.

—Dr. Morrell McKenzie, of London, believes in the identity of croup and diphtheria, but thinks the question of whether or not diphtheria is caused by certain germs or not is still *sub judice*.

—Dr. Wetherill, of Philadelphia, writes to the *American Journal of Pharmacy*, that cinchona deposits may be readily cleaned from bottles by using aqua ammoniæ.

—The Senate of Toronto University has abolished the statute which requires candidates for the degree of M. D. to write a thesis.

—The county societies of the state of New York continue to instruct their delegates to repudiate the new code.

—An appropriation of \$100,000 has been made by the Government for the erection of an army and navy hospital at Hot Springs, Arkansas.

—Dr. S. Waterman reports in the *Medical Record* two cases of diabetes, in which, though an abundance of sugar was found, the specific gravity was as low as 1.002.

—Dr. Robert C. Smedley died at West Chester, Pa., January 2. He was a homeopathic physician of prominence, and at the time of his death was engaged on a history of the underground railroad system.

—Trouble has arisen in McGill University, at Montreal, between the students and Dr. Wright, instructor, and 147 students demand his resignation, and threaten to leave if refused.

—The annual meeting of the contributors to the Preston Retreat, Philadelphia, was held last week. The report of Dr. Goodell was read, and showed that during the past year 138 patients were under treatment, and since the opening of the institution in 1866 the total number of admissions has been 1874.

—Dr. Isaac A. Doran was arrested recently at Olney, Ill., charged with forging Government drafts.

—Dr. S. M. Ballard, a prominent physician and land-owner, was robbed of \$2,700 in cash at his isolated farm in Audubon county, Ia., recently.

—The smallpox is so severe at Salem, Va., that the public schools have been closed.

—The latest cure for alcoholism is the "Kala nut." It is said to implant an utter aversion to all forms of alcoholic beverages in those who eat it.—*Credat Judeus*.

—Dr. E. M. Snow, of Providence, justly remarks: "On account of the weekly variation, both in the total mortality and in the items of it, weekly reports of mortality in any small city are misleading and deceptive, if used as a standard for the true rate of mortality, or for comparison with the mortality of other places."

QUERIES AND REPLIES.

W. H. K., III., asks for the experience of our readers in treating Ascaris, or Oxyuris Vermicularis.

F., of Ala. May a physician accept from a county, by the year, the medical treatment of its poor-house inmates at a stipend, appropriated and tendered by the commissioners' court, without violation of medical ethics?

Ans.—Yes.

MARRIAGES.

EASTMAN—DAVIS.—In Newbury, N. H., December 14, by Rev. S. L. Eastman, Oliver D. Eastman, M. D., of Piermont, N. H., and Addie D. Davis, of East Haverhill, N. H.

MATHER—EATON.—In Chester Depot, Vt., December 13, by Rev. A. R. Wilson, Dr. F. P. Mather and Mrs. M. K. Eaton, both of Chester.

PEASE—HEDDEN.—On December 25, 1882, at the residence of the bride's parents, Orange Valley, N. J., by Rev. Joseph A. Ely, Dr. Charles E. Pease to Mary A., daughter of Morris and Martha L. Hedden.

POLLARD—GOODRICH.—In Cavendish, Vt., December 31, by Rev. Foster Henry, Julian A. Pollard, M. D., of Springfield, and Lizzie M., only daughter of Christopher W. Goodrich, Esq., of Cavendish.

SHAFFER—DAVIS.—At Cream Ridge, N. J., Thursday, December 7, 1882, by the Rev. E. E. Moran, George W. Shaffer, M. D., of Philadelphia, and Lizzie H. Davis, of Cream Ridge.

LOCKWOOD—LITTLEFIELD.—In Woodstock, Vt., December 27, by Rev. Francis W. Smith, Dr. Edward B. Lockwood, of Portland, Me., and Luna E. Littlefield, of Woodstock.

GAY—McRITCHIE.—At the residence of Mrs. Howel, on January 10, 1883, by the Rev. Jas. Stacy, D. D., W. Fred Gay, M. D., to Miss Maggie McRitchie, all of Newnan, Ga.

DEATH.

STETLER.—In this city, on December 20, 1882, John G. Stetler, M. D., in the 60th year of his age.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

A chalybeate that has all the virtues and none of the defects of all the present official preparations of iron.

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts.,

PHILADELPHIA.

We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from \$15 to \$33, according to the number of currents. 1337-1351

WAS IT GLANDERS?

BY G. LAW, M. D.,
Greeley, Colorado.

W. B. W., aged 33, occupation livery-stable keeper and proprietor, doing much of his own work. Was born in Illinois, and lived there until seven or eight years ago, since which time his home has been in Greeley, Colorado. During his residence in Illinois, he had suffered occasionally from intermittent fevers, but not enough to produce any obvious cachexia, or to render him in any sense an invalid. He supposed himself to be in sound health—was, certainly, of a vivacious and lively temperament.

In September, 1880, he came down from Leadville, in this State, where he had been temporarily doing business, to Greeley (his home), suffering from a moderately severe attack of inflammatory or muscular rheumatism. This illness was of short duration, as my books show that only three visits were made.

He had no further medical treatment until May 19, 1882, when he called at my office and stated that he had a chill on the previous day (18th), followed by fever and sweating. Prescribed quinine and a laxative.

From May 22 to May 27, I made him four visits at his home.

Symptoms.—Illness ushered in with a decided chill, followed by fever and sweating, accompanied by costive bowels, some headache, moderately furred tongue, a general sense of pain in the back and limbs, and followed by a daily remission.

This train of symptoms repeated itself up to and including the 26th, but with daily diminishing intensity.

On the 30th of May he was well enough to be and was in the stable attending to his business.

June 3. I prescribed for him in my office—a chill and fever having occurred on the previous day.

On the 5th of June the chill, etc., recurred.

His case was treated from May 19 until October 7 as an obscure and anomalous form of intermittent, and believed to be such because of the symptoms, and that the free use of quinine only seemed to manifest any control over it.

On the 5th of June, by my advice, he bought a bottle of quinine, and took fifteen to twenty grains of that drug once a week until October 7, with the effect of so far controlling the malady that he was constantly able to attend to his business, and did not further consult me, or any other physician, until that date, when he came into my office complaining of a cough and some pain in his chest. A careful stethoscopic examination of the chest revealed nothing of any consequence in that cavity. Prescribed for a common cold (carrh).

October 13. Consulted me again in my office. Was now free from cough and pain in the chest. Has had no chills since some time previous to the consultation of October 7. Is now suffering from severe pain distinctly localized in the right leg, on the inner aspect and one inch below the knee joint. Said his urine had a "queer," cloudy look in the vessel on that morning. There was no swelling whatever at the point complained of as being painful; neither soreness to digital pressure. I had him leave me a sample of his urine,

which I examined by heat and nitric acid for albumen; result negative, and with like results for glucose by both Trommer's and Fehling's tests. The urine was loaded with phosphates. I concluded, upon the whole, that the pain now complained of must be rheumatic, and that it might be expected at any time to put in an appearance in a more decided form in other localities. So salicylate of soda was prescribed.

On the 14th, 8 p. m., I was called to his house and found him in bed suffering agonies of pain in the right leg just below the knee joint. He had also a chill at 4 p. m., and at the time of my visit a temperature of 104° . Morphia, hypodermically, brom. potass., grs. xxx per orem, to alleviate the severe congestive headache. To continue the salicylate.

15th, 8 a. m. Passed the latter part of the last night quite comfortably. Temperature 100° ; almost free from pain. Moved the affected limb quite freely to show how much better it was. Not the slightest swelling. 8 p. m., 15th. Chill came again at 4 p. m. Temperature now 104° , and the leg pain as severe as ever, but says his head does not ache; morphia hypodermically.

16th, 8 a. m. He sweated freely two hours after my visit last night, and soon became quite easy, and passed in the main a comfortable night. Temperature 100° . Scarcely any pain in the leg, can move it about quite freely; no appreciable swelling. Urinates quite freely. I took a sample away with me and examined as before, with negative results. Ordered quinine grs. x. at once. Continue the salicylate. 16th, 7 p. m. Chill came again about 4 p. m. Temperature now 104° . Pain in the leg as severe as ever; complains of very little pain anywhere else. Mind not clear. Morphia hypodermically; increased the salicylate; quinine grs. x. at once.

17th, 8 a. m. Found about the usual remission. Temperature 99° , ears ringing, passing less urine. Stopped the salicylate, and put him on potass. acet. and mur. tinct. iron. 7 p. m. same day. Had no chill, temperature 101° , not much pain in his leg, no headache. Left morphia to be given per orem during the night if needed. His bowels have not moved for two days; ordered a dose of sal. Rochelle.

18th, 8 a. m. Passed a comfortable night, and did not need to take the morphia; bowels have not moved. Repeat sal. Rochelle, and use syringe at noon if the bowels have not moved by that time. Continue potass. acet. and mur. iron. Allowed him to sit in an easy chair while his bed could be changed and chamber aired. 8 p. m.,

18th. On returning to his bed at 2 p. m., he had a violent chill, but not of long duration. The pain in his leg returned, but was not so severe as usual after these rigors; temperature now 102° ; has had some sweating, but not so profuse as hitherto. Bowels moved freely after using syringe at noon; no tympanites or soreness.

19th, 8 a. m. $\frac{1}{2}$ gr. morphia by the mouth enabled him to pass a fairly comfortable night. He manifests—and has for days past—a moderate delirium, is conscious of it himself; complains of clicking sounds in his ears, is not deaf; temperature 101° ; drinks a good deal of water, as he has from the beginning; is urinating freely; urine no longer cloudy when cold, is alkaline in reaction. Throughout this last attack he has complained of pain only in the right leg, inner aspect, just below the knee joint, and headache for two days only. Insists now that he has no headache and no pain in the leg. Tongue remarkably clean, moist, and natural; has not yet had the slightest nausea. I can find no enlargement of either liver or spleen, nor soreness over either organ. There is not now, nor has there been at any time, the slightest icteroid hue of the skin or conjunctiva. The discharges, when procured from the bowels, have all along been normal in color. On examining his back over the region of kidneys to-day, I noticed a papular eruption of a bright red color, covering a space 3×3 inches. He insists that it is not sore. It could hardly have been caused by pressure. His appetite is good, and has been from the beginning, as I know from having observed him eat his breakfast repeatedly. Still there is an indefinable something about the case that tells me he is not convalescing. 19th, 8 p. m. Situation unchanged save a slight rise in his temperature late in the day; no chill, no pain in the leg, no headache. Still complains of a stuffed feeling in his ears, and clicking sounds. When left to himself, imagines a dual existence, one of which is his favorite horse Tabor.

20th and 21st. During both these days there was no change, save on the 21st there appeared three distinct erythematous papules on the right leg, occupying the region that had been so painful, each in size that of a twenty-five cent coin, circular in shape, and distinct by being separated from the other by a few lines of apparently unchanged tissue. Also two papules of the same character on the left side of the neck, one above the other, exactly on the sterno-cleido mastoides.

22d, 8 a. m. With the aid of $\frac{1}{4}$ gr. morphia he rested fairly well last night, but seems more delirious; tongue for the first is coated, breath

slightly fetid, says he has no headache. The eruption more pronounced; complains of some pain in his right wrist but of none in the leg; bowels slightly tympanitic. He will not admit that there is any pain or soreness in them. 7 p. m., 22d. Bowels have moved spontaneously three times during the afternoon, discharges thin, almost black, nearly odorless, and not accompanied by pain; decidedly tympanitic; pain gone from the wrist joint. Right side of the face swollen from a point just anterior to the angle of the lower maxillary upwards to the temporal region over the zygomatic arch, in a ridge of two fingers' breadth. Skin over this swelling only faintly erythematous. Complains now of difficulty in swallowing. He now occasionally hawks up a substance that looks like pus streaked with grumous blood. When raised towards a sitting posture the nose sometimes discharges a small amount of the same substance. Stopped the potass. acetate and iron and ordered mur. tinct. iron and quinine, subnit. bismuth and Dover's powder instead of morphia.

23d, 8 a. m. Did not suffer much pain during the night, bowels moved three times, the discharges black and watery, appetite gone, tympanites decidedly increased, temperature 102°; feels very despondent, is fairly rational when his attention is sharply held, but wanders the moment he is left to himself. A vesicle with a dark, bloody-looking, depressed centre $\frac{1}{4}$ of inch in diameter has come during the night on one of the papules on the neck; swelling on the face rather increased, and now has a decidedly erysipelatous look. 23d, 7 p. m. Temperature 103°, has had no pain, bowels have moved frequently, character of the discharges unchanged, mental habitude increased; papules of the same appearance as those heretofore described have appeared on the left leg and thigh, and on the forehead.

24th. No new manifestations to-day, bowels have not moved so often.

25th. Could note no change.

26th. Numerous vesicles have appeared, indistinguishable from a typical vaccine or variolous eruption. The one that first appeared on the neck is now an ulcer with inverted and clearly defined margin.

27th, 10 a. m. Had counsel called; temperature 102°. Swelling on the face covered with vesicles, ulceration on the neck deepening and spreading rapidly. Papules and vesicles situated mostly on the lower limbs, increasing in numbers; here and there a small vesicle has seemed to dry up into a black scab without ulcerating. But vesicles

one day old have generally become ulcers; breath to my perception fetid, the consulting physician calls it sweetish. Mouth cannot be opened sufficiently to permit an examination of the fauces. There has been only the most trifling involvement of any of the lymphatic glands. Quinine and iron treatment continued.

28th, at 1 p. m., patient died. I should estimate there were at least one hundred points of vesication or ulceration on his body, none of the ulcers deep or extensive except the first one that came—that on his neck. The eruption noticed on his back faded away without vesication or ulceration. After he ceased having chills, there was no profuse sweating. Never any nausea at any time. Was the case pyemia? I never could learn that he had had any sores about his person. To this end I carefully and repeatedly made inquiries. I failed to detect evidence of any internal abscess. He never suffered much pain in his back. He never complained of pain that could reasonably be referred to either liver or spleen. He never had syphilis, to the best of my knowledge and belief. His two children, aged respectively, one four years and the other two months, are really paragons of health and sound development. I asked him the question, and received a frank and I believe an honest negative.

When the papular and vesicular eruption, diarrhœa, and tympanites supervened, I warned his friends of the danger I feared—viz: that the disease might prove to be glanders—and urged carefulness in avoiding contact with his secretions. My counsel was inclined to diagnose pyemia.

Some time last spring, he (W. B. W.) had in his stable a mule supposed to be glandered; he finally had this animal taken out and killed. Later they had in the same stable a horse affected with a "nasal gleet." This animal was turned out in the "range," and what has become of him no one seems to know. Besides, they kept the horses of transients, and may have repeatedly had diseased animals in the stable unwittingly.

Was the case glanders, contracted by inhaling or swallowing the virus in a minute quantity, leading to a gradual and chronic evolution of the detailed symptoms? That it was not acute glanders, starting from a local reception of the virus, I think must be admitted.

Did the disease in its entirety date from May 19th, or was the final malady—glanders or pyemia—engrafted subsequently upon a malarial cachexia? During twelve years' practice in this town and state, I have not met anything that I have called malarial fever in the common accepta-

tion of that term, in the person of any individual who had not resided at some time in his or her life in a distinctively malarial climate, until the present year, 1882.

Two patients besides W. B. W. have been under my care at intervals during the last three months, manifesting symptoms indicative of malarial intermittent. Both have certainly derived great benefit from the use of quinine. They, unlike W. B. W., had sallow skins, furred tongues, enlarged spleens, and more pain in the region of the liver and spleen. At all events, I took or mistook the alternate exacerbations of rigor, fever and sweating in W. B. W.'s case for a malarial manifestation. I think, now, it was not such. When the macular eruption appeared, the leg pain subsided; but the general condition of the patient being evidently worse, now what? Syphilitic fever accompanied by erythematous syphiloderm? No. If there had been pyemic metastasis to the leg, it ought to have distinctively involved the knee joint, and the leg should have been swollen.

I will not take up space to recount the symptomatology of either glanders or pyemia. A good description of glanders may be found in "Wood's Practice;" the same things, essentially, in Neimeyer's; "Miller's Surgery" treats the matter more in detail than either. I cannot find that cases of glanders have been frequently reported in the journals during the last eighteen years.

I could have had a post-mortem examination if I had asked for it; but having barely escaped with my life less than a year since from the effects of post-mortem poisoning, I feared to make it on the body of W. B. W.

CLINICAL STUDIES OF INEBRIETY.—TREATMENT BY MORAL MEANS.

BY T. D. CROTHERS, M. D.,

Supt. Walnut Lodge, Hartford, Conn.

A physician of Chicago, who should have known something of inebriety, announced gravely that many thousand inebriates were cured every year through the gospel temperance movement.

Another physician, quoting this expression, asserted that fifty thousand inebriates had been permanently restored in two or three of the Western States. Equally extravagant assertions coming from clergymen, reformers, and parties who know practically nothing of the subject, have gone out as facts, upon which the most erroneous theories and absurd efforts have sprung. The best results from the most careful studies of all these moral movements to reach inebriates, indi-

cates from one to three per cent. only as cured, and these through means and forces that are unknown to those who put them in operation. If this were all, there would be much to commend it in the absence of better means; but the fact is susceptible of the clearest proof, that a large per cent. of all these cases who are not restored by this means are made worse. The failure of the effort to recover after the mind has been wrought up to the highest pitch of expectancy, trusting to means and forces that are inadequate to reach the organism, is followed by a degree of mental degeneration that is difficult to overcome. Destroy the element of faith and hope in any disease, and the possibility of cure is more and more uncertain. Pledge a hundred men to stop the use of spirits at once, inspire them with full faith in absolute recovery; then if they fail, giving way to the first temptation, the last state of those men is worse than the first. The worst cases that come to asylums are those who have tried the pledge, and societies, and been converted by the gospel temperance work, and failing in all these, resort to the asylum with no expectation of being cured, nor with confidence in any means or method of treatment. The principles are false upon which the temperance movements and all moral efforts to cure the inebriates are based, particularly the theory that inebriety is the result of a deficient will-power, built up in one case from want of sympathy and charity, with misfortune, bad company and bad influences; and in the other, from evil surroundings and want of faith in a higher life, of conversion and nearness to God. To remedy the first state, the various societies of temperance are banded together, who seek by mutual counsel, sympathy, and pledging, to abstain and restore the inebriate. The last state of sinfulness which encourages or produces inebriety, is to be met by church methods for conversion and change of heart, uniting with the church, and by relying on God's grace be saved from all temptation or relapse in the future. A method called the gospel temperance movement is a combination of the two, and is urged with great energy in many sections. Other efforts along this line, only varying in particulars, are common to every town and city in the country. A general review of these methods will indicate the causes of their practical failure as curative agents, and show how that their real value is only in educating and preparing the way for a wider view of the subject.

1st. The Method of Societies.

From 1870 down to the present time, there has

been a constant succession of temperance societies of all grades and forms of organization, that have come and gone like the leaves on the trees. From the Washingtonian movement down to the last society formed, there has been a remarkable instability and restless change in these attempts to reach the inebriate.

At one time they are very popular, attracting great attention, then fall into decline.

The most enthusiastic supporters often become prominent examples of its failure. The inebriates who are brought under its influence, and feel the power of its sympathy and association, may, for a time, recognize, through pride and gratitude, a curative force; but sooner or later the diseased organism attains the ascendancy, and relapse will follow. The society by its efforts takes the place of home, but cannot do more than a loving wife, children, brothers, sisters and parents. It may invest these influences with a formality and stateliness that a home cannot give, and exact some public recognition that family and home life do not require.

In many cases a society may exert a stronger influence than a home, but in the large majority of instances, the latter is the central governing power of life. If the influences of a home and friends have no power to restrain the inebriate, it is not possible to expect such results from the same forces applied through societies.

Yet all experience furnishes examples of cases who have recovered by the power of both of these means. One hundred inebriates are taken into temperance societies and pledged to reform, and are helped as far as possible to this end. On a certain number these influences will be powerful enough to enable them to abstain from spirits for an indefinite time, depending upon conditions unknown. In a hundred cases of inebriates who have a warm circle of family influence to restrain them, some will be found who will yield and become temperate for an indefinite time.

Yet all deductions from these cases as to the value of this as a plan of treatment, would be misleading. In the second case, which presupposes a wilful, sinful heart, and seeks, by the power of conversion, to build up a new life of freedom from spirits, the avenue to the organism is through fear and emotion. All authority of the Bible is cited to alarm the patient with the dread of future endless punishment, and all the emotions are aroused in efforts to save himself by trusting simply to faith and the exercise of prayer. The psychological power of example and the pressure of surroundings may concentrate the

mind and energies in this direction, impressing the organism so profoundly as to alter the diseased impulse for a time, and perhaps permanently. The patient is converted, and filled with a new hope and impulse which may dominate over the disease. How long it may last, or how far he can rise above the entailments of the past, are questions which only a wider study and acquaintance can answer. The power of religious faith over the diseased organism cannot be estimated by any known means at present. In almost every church and community many cases may be found who have tried these means and failed sooner or later. Some for a time have been shining examples in church and community, then have suddenly disappeared from observation.

Lastly, may be mentioned the gospel temperance efforts, which combine the power of the pledge and conversion with the fellowship of the church and society. These methods have attracted much attention and aroused great expectations in the minds of many.

From the pulpit and rostrum are heard the confident predictions that these influences and methods of treatment will effectually break up the inebriety of the age.

As means for the cure of inebriates, they are literally failures, but as methods of prevention by awakening the public to a sense of the danger from inebriety, and pledging men who are temperate to avoid this source of danger in the future, they are doing much good. These movements are evidences of widespread alarm, and also hints of psychological forces whose march is governed by laws yet to be discovered.

The cases cured by these methods are from the influence of the mind and the body.

A condition now well recognized by psychologists, but one of uncertainty in its practical application as a remedy. The weakened brain and nerve energy of the inebriate are extremely susceptible to powerful emotions and the contagion of example and surroundings.

Through the influences of religious appeals, the mind may be so impressed as to paralyze the diseased action, altering the direction and force of all mental power in the future.

This may be termed a form of psychical traumatism in which the brain functions are changed in some unknown way.

The chronic inebriate who suddenly changes all his past life and habits from conversion and religious impulse, has received a physical shock to the nerve centres, altering the direction of their energy, which in some instances may be permanent.

In much the same way that fear, grief, or any sudden and overwhelming emotion may change all the future health and character of a person. It is clear that the organism must be in a peculiar state to be impressed by these psychical impressions from religious influences, and the sympathy of family and friends, if brought to bear on the diseased brain at the right time may check inebriety for a time and perhaps permanently. But it is equally obvious that such knowledge of this state is not always attainable, and the application to the treatment of inebriety is not theoretical or practical.

The value of moral means can be seen in some of the so-called faith cures, where prayer and strong impulses are followed by undoubted recoveries.

The following are some instances that are more or less common: A lady who was in the last stages of consumption recovered after the return of her husband from the army whom she supposed had been killed. A case of chronic rheumatism of many years duration got well, dating from the alarm and narrow escape from a burning building. An inebriate fell through the ice and was nearly drowned. The fright and alarm was so great that he stopped from that time. Three inebriates took refuge under a tree in a storm and were all stunned by a stroke of lightning. One drank harder than ever from this time, the second never used spirits again during life, and the third was a sober man for ten years, then died after a few weeks' drinking. All were inebriates. One was precipitated into worse stages, another was cured permanently, while the one remaining was benefited for years, all from the same electric current acting on the organism.

A bar-keeper having been a chronic inebriate for years, at the request of his wife, suddenly stopped drinking, remaining sober ever after, while in the same business, exposed to same influences and conditions. In one case, the simple warning and entreaty of a clergymen will rouse a man to change his life; in another the prayers and entreaties of Christian people for years will fail.

Thus the efforts to cure inebriety, as seen in the results furnishes the most contradictory evidence in cases that are cured and made worse by the same means, and under apparently the same condition. The unmistakable conclusion is that inebriety as a physical disease is governed by physical laws of whose operations we are ignorant. Where moral means are successful, it has been along the line of law, and where it has failed, it has been inharmonious with the law.

The value of prayer and faith and the influence of home and society can only be made effectual when used in connection with physical means, and without this it must of necessity fail. The bar-keeper might be pledged to stop drinking and continue well in the same business and remain ever after, and yet this must be an exception to all rules, because all the conditions are unusual.

The chronic case of rheumatism or consumption may recover from various obscure causes that act suddenly. The influence of religion and society may bring the same results in cure, but in these cases there is a mystery and uncertainty that cannot be utilized.

It is obvious that all cures from these means must be exceptions to the rule, and depend on some accidental combination of circumstances. Also that moral means as adjuncts, and in connection with physical appliances may be of great value. Place the patient in good surroundings, removed from alcohol, under medical care, then bring all the power of moral suasion, and its value will be apparent, for the reason that the organism can be made to sustain and carry out the moral impulses that have been encouraged as started. The inebriate who relies on the moral force of religion and societies to the neglect of positive physical means will fail, just as certainly as he would if he trusted to these means for relief from malaria or typhoid fever. The statements of many cures from this means alone, cannot be established by observation or clinical study. It is impossible for temperance societies or church efforts to cure inebriates, simply because they have no appliances, and cannot bring remedies that will meet the wants of the case. The nerve exhausted and worn out inebriate needs rest and food principally. His will power and higher moral faculties are powerless in opposition to the diseased organism, or remove the almost indefinable pain which comes from the starved nerve centres.

A physician who is a moderate drinker has sent me the following study of a Murphy temperance movement in his town. In all probability this fairly outlines the results of other similar efforts. Twenty-two men who were moderate and excessive drinkers, signed the pledge, professed a change of heart, and promised to follow a better life. They were men of families, homes, and operatives in factories. None were idlers, all could be and were employed steadily. Eighteen were very enthusiastic and positive that they were permanently cured. All united with the Good Templars, and eleven joined the church.

Three months after the revival closed, seven had relapsed, three had been expelled from the lodge, and two taken back on probation. One year later, nineteen had relapsed, in another year, only one continued temperate, but occasionally drank beer and cider. Of the twenty-one who had publicly relapsed, nine were more drunken than before, and in every way sank lower in health and morals. The following cases were evidently made worse by those efforts, and are mentioned to call attention to this subject, rather than conclusive evidence of the danger of these means.

A. B., of neurotic inheritance, who began to use spirits soon after puberty, was at twenty-five a junior partner in a large house. He drank frequently to intoxication, and lived a fast life. He became converted in a temperance revival, joined the church, and was sober for many months, then relapsed and drank harder than ever. Refusing all aid, he was indignant at the church and society for its failure to perform a miracle in his case. He seemed from this time to have lost all faith and respect for every good influence; was turned out of his place of business, and is now an inmate of an insane asylum.

C. D., of unknown parentage, was a prosperous grocer, who drank frequently to intoxication after some domestic trouble. He was of a buoyant, hopeful nature, always confident he could resist the temptation and not drink any more. Was proud, energetic and of good habits except drinking. He joined a temperance society, and spent his evenings lecturing and working to help others, becoming very prominent in the Order. A year later, he relapsed suddenly after a period of prolonged labor in lecturing and visiting lodges. From this time he never recovered, but drank steadily until death. He lost faith and confidence in any effort to be benefited, and displayed low moral traits and profound weakness of both body and mind. He made no effort to help himself, and resisted all entreaty to stop the use of spirits.

C. F. was the son of a clergyman; of a nervous temperament. He began to drink in college, and at twenty-four, when engaged in the profession of law, was a hard drinker. At thirty, he was a periodical inebriate, much reduced in mind and body. He was converted under the teaching of Moody, and for six months lived a sober and temperate life; then relapsed, and drank continuously for over a year, until he died of pneumonia. Previous to his death his mind lost its vigor, and he made no exertion to help himself, having but

one ambition, and that to get all the spirits he desired. Before this relapse he was cheerful and confident of the future, seeming to work with energy and courage, which gave much promise of success. After the relapse he was changed both in character and disposition.

G. H. had a strongly-marked history of insanity in his family. There was no record of his drinking until he returned from two years' residence abroad, where he became an inebriate. For three years after he came home he drank continuously; then reformed, joined church, and became an enthusiastic supporter of the temperance cause. Finally, he relapsed, and, like the others mentioned, rushed precipitately to the lowest stages of inebriety. Nothing could induce him to stop in his mad career. He was brought to the asylum a complete wreck in hope and faith. He had no disposition to help himself, and would not use the common means for recovery, but sought every opportunity to relapse. After three months' treatment, he went away and drank severely, then was taken to an insane asylum.

These cases are hints of what a wider knowledge will reveal, pointing to certain states of failure of the mind, following disappointment from relapse, or reaction from failure to recover. The weakened brain and nervous system reacts with difficulty from disappointment of any kind. Inebriety leaves the mind and body more sensitive to the sharp friction and strain of life. The conserving powers are exhausted, and not unlike a ship which has breasted the waves of the ocean for many years, becoming strained and weakened, are liable to go down in any storm that may arise.

Diseases that are contagious are more fatal in inebriates, and injuries are more complicated and also more dangerous. All methods of treatment should recognize this, and seek to remove every influence which produces any undue strain on the organism. I conclude from these facts, confirmed by a large observation, that moral means alone, as a method of cure in inebriety, increase the strain and lessen the power of nature to respond to the action of natural means. This is done by the application of means to one part of the organism to the neglect of the other, hence the strain and irregularities which are sure to follow.

—Mr. N. Stevenson, of London, uses a small Swan incandescent lamp to illuminate the cavity of the mouth in dental operations. It is fitted into a vulcanite cup, which acts as a prop to keep the jaws apart.

CENTRAL AMERICAN MEDICAL CURIOSITIES
COLLECTED FOR THE MEDICAL AND
SURGICAL REPORTER.

BY FERD. C. VALENTINE, M. D.,
Of New York.

(See pp. 397 and 617.)

Liquid amber is used externally as a discutient, to stimulate granulation, and is applied to rheumatic joints. In gonorrhœa, leucorrhœa, vesical catarrh, and dysmenorrhœa, it is given in tablespoonful doses one to four times daily, mixed with honey. An infusion of the bark and leaves is used externally in rheumatism, and to dress the wounds of those who have been lashed. The latter application of this remedy is called for in but one of the republics of Central America, and happily promises to become obsolete, as the advancing spirit of the age is asserting itself against this horrible means of punishing political offences or of gratifying malevolence.

Maguëy, a variety of the agavæ, would merit extensive discussion in an article upon the very many possible industries which should be developed in Central America. Immense plateaus are covered with it, and the elaboration of its fibres, which are strong and pliable, and of a silky-hempen appearance, costs almost nothing. Medicinally the juice is used, which readily undergoes alcoholic fermentation and becomes the *pulque* of Mexico, an exquisite stimulant. The unfermented juice, which exudes copiously from cuts in the trunk of the plant, is used in injections in dysmenorrhœa and in tardy parturition. Enemas, which are also used for these purposes, are composed of two ounces of maguëy juice, four ounces of fresh milk, and two ounces of honey. The liquid is warmed and injected "al calor del cuerpo," which is about 99° Fahr. Infusions of the root and leaves are credited with anti-specific properties in syphilis and malignant ulcers, used topically and internally. The fresh juice mixed with flour acts as an unreliable sinapism.

Maize is the staple cereal of Central America, occupying the position that wheat does in this country. Although wheat flour and its main product, bread, is growing more in use, the "*tortilla*" is among the vast majority the staff of life. As this article of food, so abominable at first to the stranger, is hardly of medical interest, except, perhaps, as a cause of disease, I reserve its description for another time.

Maize is stewed and given as an orgeat in pulmonary affections; it is toasted and ground and given in lieu of coffee, when the latter is not

tolerated, and a very agreeable drink is made of slightly toasted yellow corn, ground and boiled, with milk and sugar subsequently added. This is given, freshly prepared, to women who are suckling their infants, with a view towards stimulating the flow of milk.

Green corn is crushed, mixed with water and some aromatics, and allowed to ferment, forming one of the various kinds of native *chicha*, all of which are more or less inebriating. In some parts of the tropics corn is used as a substitute for barley in the production of beer, which, when it has grown "*abgelagert*"—say about six weeks old—is quite palatable.

The marshmallow is, perhaps, one of the most used drugs of the Central-American botanic materia medica. The leaves are bruised and boiled in milk or water, and used as a poultice whenever it is required, and frequently when it is not. Painful hemorrhoids are treated with sitz-baths of hot milk, in which the marshmallow leaves have been boiled. A decoction of the root is much used in all thoracic affections, and in those of the kidneys and bladder; likewise it is employed as a wash and gargle in stomatitis, inflammations of the throat and eyes.

Chamomile flowers in cold infusion are considered a tonic, and particularly useful in indigestions and for convalescents. The infusion in hot water is given in large doses with emetics. The powdered flowers, in half teaspoonful doses thrice daily, are used as an antiperiodic without appreciable success. The hot infusion is also given in injections for colics, and *per orem* it is considered the best possible means to increase the lochial flow and to calm after-pains. Oil of chamomile is frequently used hot in mastitis.

The marañon (*anacardium occidentale*, Linn., cassuvium pomiferum, Lam., casher-nut), is well described on pp. 1576 et seq. of the U. S. Disp., 1878, in all parts except where it is claimed that the kernel is eaten raw. The few foreigners who have made this mistake have had cause to regret it, in the diarrhœa they produced, which resembles that of croton-oil poisoning.

The fruit is delicious, and, perhaps, from the suggestive shape of the seed, which grows on the outside—almost separate from the fruit—it is considered aphrodisiac. The wine prepared from the fruit is really very fine. The oil, which can be easily extracted from the seeds, is quite a vigorous and prompt epispastic.

The seeds are toasted and are added in the proportions of one part to three of chocolate to give it a better flavor, and "render it more nutritious."

Infusions of the buds are used as gargles in quinsy and ulcerations of the throat.

A favorite diarrhoea mixture in Central America is made of eighteen marañon seeds, peeled and ground, a pint of common aguardiente and sixty drops each of stronger ammonia and laudanum, which are shaken together daily for a week, and given in tablespoonful doses twice or thrice in the waking hours.

The root of the common heliotrope is sliced, dried in the sun, and reduced to a fine powder. It is then given in half-drachm to drachm doses, with a little honey, as a purge.

Mechoacán (American bryony?) is prepared and used like the preceding; "When copious evacuations are desired, as in dropsy or apoplexy, half an ounce of cream of tartar is mixed with a drachm of the powdered mechoacán root."

Muskmelon seeds are ground and mixed with rice and made into an orgeat, which is given hot in "internal inflammations," which may mean anything, but more frequently nothing.

Honey is given in three to four tablespoonful doses, mixed with aromatic infusions, to calm the pains of dysmenorrhœa. It is used externally as a "plaster to clean foul ulcers" and upon bruises. The wild honey of Central America is easily gathered, as the bees do not sting.

Mustard is a stimulant and diuretic, and the whole seeds are given in tablespoonful doses twice to thrice daily in tardy digestion, scurvy and dropsy. Ground mustard is used as an emetic, and it is claimed to be especially useful in paraplegia. It is applied as a sinapism or poultice, mixed with two or three parts of flour in what are called the lethargic diseases, such as fevers accompanied by stupor, and as a derivative in local inflammations. Thus in gastritis, or affections that are so diagnosed, it is applied to the abdomen, and in inflammations of the brain, eyes or throat, it is applied to the nucha. In similar affections, ground mustard is added to the foot-bath. Mustard whey is made by boiling an ounce of ground mustard in a quart of milk until the latter coagulates. It is then strained and given a pint per diem, in gout, dropsy and paralysis.

All parts of the various kinds of orange are used medicinally. Sweet oranges (and they must be very sweet, indeed, and exquisite withal, to be worth 1 real or $\frac{1}{2}$ of a peso—84 cents—a hundred) are allowed patients in putrid and bilious fevers. This is an exception to the prevailing rule, as usually all fruit, fresh air, light and water, are tabooed in any acute illness. Infusions of the young leaves and flowers are freely given to pa-

tients with flatulence, hypochondriasis, palpitations and "faintings." Infusion of the bark and root of the sour orange is said to promote menstruation and the lochiæ, and a decoction of the leaves is given to children with convulsions. Sour orange juice, mixed with honey, and a decoction of copalchi, cures old intermittent fevers. A tablespoonful of each is taken early in the morning fasting.

A favorite and very useful drink in dysentery is made as follows: Three ounces of flaxseed are boiled in two quarts of water, until it is reduced to a quart, an ounce of manna is added, as is also the juice of a sweet orange. This is drank hot or cold in unlimited quantities in place of water. Whether this must receive the credit, or whether the free use of ipecac shall be considered the cause of recovery, I am hardly prepared to state, except my own case, where four months of uncontrollable dysentery promised to gather me to my fathers, be at all a criterion. Yet, again, there were many elements in my case which may have contributed to my recovery, and I might have been relieved of my suffering without the orange-linseed-manna combination; still, since then I have treated no case of dysentery without it, and slight cases with nothing else, and was never caused to regret it. A "resolutive ointment" is made by cutting sour oranges into little bits and boiling them down to their greatest possible density. The resultant almost liquid mass is applied to swellings of all kinds, and is said to be very efficacious in arresting the secretion of milk, if applied warm two or three times daily to the breasts. Orange-blossom ointment is made by frying four ounces of the blossoms together with an ounce of lavender leaves in two pounds of lard over a slow fire. When they are thoroughly fried, the whole is strained and saved for use. The ointment is very popular for neuralgias and rheumatism.

The medlar, (*mespilus germanica*, L.,) is found in very large quantities in Central America; the seeds are added to any orgeat to make it diuretic; a strong decoction of the bark is given in doses of a quart a day in uterine and pulmonary hemorrhages, and the powdered bark is used locally in epistaxis and to control the bleeding of slight wounds.

Origanum is held to give great sexual power, to be a neurine and carminative. The powder may be mixed with food, and "the infusion has cured hiccough which not even the best relic could relieve." My friends among the clergy of Central America explain this matter readily. The igno-

rant classes go to priests to have them bless them or apply some relic to cure their sufferings. The ignorance or extreme faith of the applicant, and the imaginary character of the affection, frequently causes this procedure to be crowned with satisfactory results, but the educated priests never omit to counsel the sufferer to seek a physician's advice. The priest, saint or relic of course, get the credit and candles in successful cases of this kind.

Licorice.—The leaves and roots are used in infusions and electuaries in coughs and "side-ache." Decoction of licorice root with plantain root are prescribed in all presumed renal affections.

Urine as a remedy is used not only by the aborigines, but even by the better part of the lower classes of those who are civilized, "to frighten off fevers." And it does it when all other treatment has failed, perhaps because of the careless or inefficient manner in which drugs have been used. I speak emphatically, although I have never prescribed it, yet have trustworthy reports of cases who drank some six ounces of the fresh urine of a human female just seven years of age, fasting, and had no return of the fever. It is said that one dose is sufficient for all cases, which undoubtedly is encouraging. However, I shall continue the use of quinine, arsenic and eucalyptus, notwithstanding the good reports I have of the use of urine.

Decoctions of urtica, called *chickicaste* by the Kickáý Indians (the learned editor of the REPORTER can give the origin of Kickáý words—that is the way it should be spelled in English—better than I) are used as a diuretic in dropsy and obstinate gonorrhœas. The leaves are applied to paralyzed limbs, and most cruelly under the tails of horses and mules when the animals are exhausted by a long voyage. It is satisfactory to note that I have treated several fractures in, and made some autopsies of people who have made this experiment.

Decoctions of Brazil-wood are considered tonic, and are used in dysenteries, and particularly the chronic diarrhœas of children. The adult dose is twelve to sixteen tablespoonfuls daily.

The juice of the carica papaya, both of the tree and fruit, is given in teaspoonful doses mixed with three of water as a vermicide. This "vegetable pepsine," as it is called, is a powerful digestive, and should be investigated, as the fruit costs almost nothing; and I believe if its active principle were elaborated in an acceptable form, it would supplant animal pepsin. In many parts of Central America tough meat is rubbed with the fruit

immediately before preparing it for the table, and becomes remarkably soft.

Were not the Grimm brothers the authors of the fable of "the man who could not shiver?" The tale is suggested by one curious Central American treatment for paralysis. The affected limb is held in a tub or keg full of live little fish which have suddenly been deprived of water. A rather fair-tasting fish-oil is made of various species, and used as cod-liver-oil is employed in other parts of the world. Paralytic limbs are also anointed with this oil.

Wildcat skins are wrapped around painful parts in rheumatism.

The various classes of peppers are extensively employed. A decoction of the fruit or leaves is used as a carminative and stimulant. In chronic intermittents the patient is made to swallow whole black peppers, one each half-hour for three days.

A cataplasm of equal parts of ground pepper and powdered ginger, beaten up with albumen, is applied to "side-ache," and left on the affected part for twenty-four hours.

The young shoots of the pitch-pine (*Pinus sylvestris*), an ounce, are vigorously boiled in a quart of water and strained. Of this two tablespoonfuls are given as an expectorant, a stimulant in phthisis and asthma, and is recommended in scorbutus.

The serous fluid obtained by incisions into the shaft of plantains is given in two-tablespoonful doses every four hours for hemorrhages of all kinds. It is applied to inflamed hemorrhoids, cold. The ripe fruit eaten in the morning with salt is prescribed in constipation and as a preventive of flatulent colic.

The native vinegar, rather a poor article, is made of the ripe *guineo*—a red banana.

Lead in small plates is fastened upon chronic ulcers, and mothers who would restrain their daughters' sexual appetite, cause them to wear a sheet of lead upon the abdomen. I have never seen this, consequently cannot describe the shape and manner in which this prophylactic is attached. Small plates of mercurialized lead are worn upon "cold tumors" as a resolute.

Radishes "increase the urine, excite all of the appetites, and prevent scurvy. The juice contains starch and sulphur, consequently (!?) is the antidote to poisonous mushrooms." The dose is a tablespoonful of the fresh juice in milk or wine.

Frog soup is given in all skin diseases.

Frog powder is made by toasting the live frog in an earthenware vessel (which must be well covered, perhaps lest the frog leap out) over a strong fire, which suggests the tale of the truant who

threw stones at the frogs instead of attending his Sunday-school class, which was "fun for the boy, but death to the frogs." After being thoroughly toasted, the frogs are powdered, and the powder is given in teaspoonful doses every three hours to restrain uterine hemorrhage. The powder worn in a little bag upon the abdomen is said to suppress the menstrual flow.

(To be continued.)

HOSPITAL REPORTS.

CLINICAL LECTURE ON A CASE OF ORGANIC STRICTURE OF THE URETHRA, COMPLICATED WITH THREE PERINEAL FISTULÆ.

TREATMENT BY CONTINUOUS DILATATION—RECOVERY WITHOUT OPERATIVE INTERFERENCE.

BY JOSEPH L. BAUER, M. D.

Lecturer on Genito-Urinary Surgery, St. Louis College of Physicians and Surgeons. Surgeon to St. Mary's Hospital.

GENTLEMEN: In speaking of strictures of the urethra of small calibre, coexistent with urinary fistulæ, authorities have contended that *perineal section, internal urethrotomy, or divulsion*, are absolute therapeutic necessities. They hold that no methods of dilatation will prevent a return of the coarctation, and that it is impossible to relieve the fistulæ without the suggested adjuncts. In fact, operative methods have grown so popular, that no **CONSERVATIVE PROCEDURES** are admitted. It will be my object to demonstrate the fallacy of these assertions, and to prove that these cases can be treated without any operative interference whatsoever, and that the treatment I suggest aids in the destruction of large quantities of that foreign tissue which makes up the mass of the coarctation. Besides this, operative procedures necessitate the purchase of expensive instruments, for which the general practitioner has but very limited use, and which require an aptitude of application which can only be acquired by constant practice and long experience. Hence, the old treatment by continuous dilatation is pre-eminently a practical one. It is well enough to offset this assertion by the fact that specialists have made these operations a study, hence send your cases to them. But you compel the **POOR PATIENT** to be treated at home, and have suggested operative interference for the benefit of those that can pay for them. But, *continuous dilatation* is no respecter of persons, and can be applied to all alike.

Let us now consider the case before us. This young man appeared before you ten days ago. He gave you a history of repeated gonorrhœas, with a gradual diminution, twisting and separation of the urinary stream. He has also had several attacks of retention of urine and fever. Besides this, he has had peri-urethral abscesses, which have been opened, and resulted in the establishment of perineal fistulæ, through which considerable urine passes at each micturition.

We examined our patient carefully, and found that two of these fistulæ could be seen to the right, and one to the left of the perineal raphe. Letting our finger course along the urethra, we felt the hardened, indurated portion for about one inch of its extent, and some distance from the triangular ligament, posteriorly. Our patient informed us that a surgeon had failed to introduce No. 3 English gum-elastic catheter, and that he had been advised at home and abroad that operation (perineal section and internal urethrotomy) was his only means of relief. You remember that neither No. 3 nor No. 2 would pass the stricture, and we were only successful in introducing No. 1 A. S. Our success was verified by the appearance of urine at its distal extremity. Many of you have felt its indurated, cartilaginous structure. You likewise noticed that there was very little discharge oozing from the meatus urethræ. I then described the method of treatment which we intended to follow, but may be excused if necessity demands its repetition. After introducing a No. 1 catheter, we tied it in and corked the distal opening, advising the patient to remove it whenever micturition became necessary. He was to call next day, and have the operation repeated, substituting No. 2 catheter. But, remember, I cautioned you against allowing the instrument to remain in the bladder, lest its presence might lead to the deposit of urinary salts, superinduce cystitis, or produce other difficulties which might result from locomotion. Hence, the point of the instrument was permitted to rest at the neck of the bladder. This course was persisted in daily, until No. 4 could be passed. Then we skipped a number each time, until to-day we remove No. 12 gum-elastic catheter, and introduce No. 14 steel sound. From No. 1 to No. 4 some urine oozed from the urethra alongside of the instrument; but none has since, nor has any passed through the fistulous tracts. To-day, we change our treatment; the urethra is sufficiently large to introduce a good-sized catheter, which will be done whenever micturition demands it. Our patient will call upon us every three days, and we shall then introduce successive sizes of the ordinary steel sounds until we have reached what we may suppose to be the normal calibre of the canal. We have not used Otis's urethrometer, since we do not know WHAT PART OF THE URETHRAL CANAL should be measured, in order to determine its normal calibre.

Then, gentlemen, in dealing with all surgical lesions, we must accept the most conservative methods, and only apply the knife when we are **FORCED** to do so. It has been my fortune to have witnessed the various urethral operations performed by unexceptionable gentlemen, and I have too frequently observed the unfortunate complications resulting from them. Besides all this, not one of the advocates of operative methods relies upon their results, but *invariably* the steel sound is used for a shorter or longer period, until all danger of a recurrence is averted. Clinical experience has taught us that success can only then be anticipated when we combine **DILATATION** with **CATHETERISM**. In other words, we should strive to enlarge the calibre of the urethra, exclude urine from the fistulous tracts, and prevent the irritating influence of the decomposed urine upon the stricture.

Permit me to cite the views of both Thomas Bryant, F. R. C. S., and Eric Erichsen. They require no laudation at our hands. They have been accepted authority by the most eminent men. Bryant,* in speaking of the treatment of these affections, uses the following language: "The treatment . . . must be based on the pathology of the disease; and mild means should always be preferred to forcible or cutting measures." . . . "The principle of treatment is also simple, for it is *primarily* to dilate the contracted canal; and *secondarily*, to obtain the absorption or *breaking up* of the effused inflammatory products. *The more simple the means by which these ends can be secured the better.*" (Italics mine.) "Where the first end has been obtained without the second, temporary benefit may have been effected, but no more. Where *both ends* can be gained by *simple means*, the treatment must be pronounced good. In ordinary cases of organic stricture, there is little doubt that these ends are to be secured by *dilatation* of the stricture; and by such *local treatment alone*, the majority of cases of organic stricture may be successfully overcome. Now, this treatment by dilatation may be *continuous or intermittent*. The former method is to be preferred, and should be carried out as follows: it is *certainly the most rapid and effectual* the surgeon has at his disposal, although it necessitates about a fortnight's rest. Then follows substantially the same method which I have followed in *this and two other cases*, which some of you have had the opportunity of observing last winter. I called your attention to the absence of any significant discharge when this case presented itself. This condition has grown more important; in fact, it verifies the "*breaking up*" of the *organic matter* in and around the urethra. The thick flocculent purulent material has been examined microscopically, and found to contain pus cells in large numbers, and a significant amount of *granular detritus*, which results from tissue disintegration. This *new cicatricial* material possesses *very little vascularity*, hence excentric pressure applied for some time robs it of all its nutrition, and occasions its decay. This cannot be said of any of the operative methods.

You have likewise noticed that these instruments have been introduced and retained in the urethra, without any pain whatsoever, save Nos. 12 and 14. These occasioned some inconvenience, on account of their size; they kept the penis in an uncomfortable position, allowing the clothes to bend and shift it laterally. The pains were of a neuralgic character, and subsided when the cause was removed. It has frequently been charged that this treatment necessitates the recumbent or reclining posture, in order to attain any measure of success. As a rule, these cases are connected with considerable constitutional complications, such as septicæmia, renal and vesical difficulties, which incapacitate our patients for the lightest of manual labor. Hence time is of very little importance to them, and energetic operative measures very risky, if not of questionable value. But, gentlemen, this is our second case in which we have demonstrated the feasibility of allowing our patient to be about and to engage in the prac-

tice of his particular vocation, *without any pathological disturbances*. Indeed, you remember the case of the negro presented to the class last winter, in which we had the greatest difficulty in introducing a filiform bougie. Yet he passed through the same ordeal, carrying a catheter in his urethra whilst engaged in the arduous labor in an iron foundry. Yet, in this case, we succeeded in re-establishing the normal calibre of the canal, and can to-day introduce a No. 32 French without pain or hindrance, *and no instrument has been passed for a month*, thus demonstrating clearly that we have destroyed the coarctive properties of these abnormal deposits.

As a result of the teachings of Prof. F. N. Otis, the normal calibre of the urethra is considered larger than formerly. He contends that there is a definite relation between the circumference of the penis, and the urethral calibre. Be this as it may, practical experience permits you to assume that the normal calibre lies anywhere from number 26 to a number 36 French. Hence, we can readily comprehend why the older surgeons, in estimating the urethral calibre as number 12 to 14, failed to gain those successes from continued or occasional dilatation, which you of to-day will gain, in profiting by the valuable teachings of Otis. One of the greatest difficulties which you will meet with is a CONTRACTION OF MEATUS, or anterior urethra, about $\frac{1}{2}$ to 1 inch from the external urethral opening. This will prevent a full dilatation of the deeper urethra; hence, *it is always advisable* to incise it with a bistoury, or better still with Civiale's urethrotome; YOU WILL THEN HAVE NO difficulty in continuing dilatation.

Erichsen* says: "This plan of treatment is of great use in cases in which *considerable difficulty* is found in introducing the instrument, but it has the disadvantage of being extremely liable to set up cystitis. If the treatment be continued beyond 3 days, the urine will almost always be found to be alkaline; and this is scarcely to be wondered at when we consider the way in which the bladder is, as it were, opened up to the air." I do not deny, that an instrument introduced and left in the bladder will very likely set up cystitis. But, it is not essential that the instrument should be left there. "The catheter having passed the stricture, and entered the bladder, is to be fastened in, the end of the catheter, up to its eye alone, resting in the bladder" (Bryant); or you can use the catheters with an eyelet in the centre, which would only require the instrument to be placed in the prostatic urethra. Yet I cannot understand, how the charge of opening up the bladder can be sustained. For, the instrument fits so tightly that very little air can pass in on the sides of the instrument, and none through the instrument, since it is always closed, unless at the time of urination.

Our treatment of these cases is specially applicable when urinary fistulæ are combined with them. The fact is well established, that AS LONG AS URINE IS PERMITTED TO DRIBBLE INTO THESE TRACTS, THEY WILL NEVER HEAL. Hence, you must protect the internal openings of these sinuses, and give them an opportunity to repair.

*Bryant's Practice of Surgery (Roberts), chapter xxiii., page 643. Phil., Henry C. Lea's Son. 1881.

*Erichsen's Science and Art of Surgery, Vol. ii., Chap. lxxiii., page 861. 1878. Phil. Henry C. Lea.

You will often be surprised to see the rapidity with which they close. Sometimes, and especially in old cases, you will find it necessary to inject some irritating substance into them, and produce thereby adhesive inflammation. But, this is rarely necessary. You all remember the case of McCabe. He suffered from a traumatic stricture of the bulbo-membranous urethra. He also presented an history of repeated gonorrhœas, peri-urethral abscesses and urethral fever. There were five distinct urinary fistulæ leading through the scrotum and perineum; in fact, both of these parts were honeycombed by sinuses, and a large complement of cartilagino-cicatricial tissue. A hardly perceptible amount of urine passed through the urethra; and when micturating, the perineum and scrotum were transformed into a watering-pot, as it were. The patient was attenuated, pale and septicæmic, and presented evidences of general anasarca. When I first examined him, I could not introduce a filiform bougie; this was even futile, when placed under full anaesthesia. It took persistent labor before we succeeded in introducing a very fine uterine (bulbous) probe. The cicatricial tissue was hard and unyielding. The penis was deformed, and our patient impotent. But, what a splendid result was attained! This treatment was carried out in all its details, and after a confinement of three weeks in bed, our patient gained in health, weight and appearance; the urinary fistulæ healed up, and at present he passes his water freely, and can introduce a No. 22 steel sound, and can attend to his business without hindrance.

Is there any other method that can claim these advantages? Can the advocates of perineal section, divulsion or urethrotomy claim equally good results, with an equal absence of danger? I think not. Let us see. In my lectures last winter I cited the case of Bowen, who had a large cicatricial stricture, complicated with numerous urinary fistulæ. No. 6 sound could be passed with some resistance. He was evidently under the influence of septic infection; in fact, a more deplorable picture of constitutional decay could hardly be imagined. And yet, a prominent surgeon of this city thought that perineal section and internal urethrotomy were the proper therapeutic adjuvants, and so they were; both assisted him in ending his earthly career hurriedly. I do not hesitate to say that continuous dilatation would have offered him a better chance of recovery, since it would have spared an already disturbed constitution from any additional shock. I have taken occasion to present you the clinical reports of our distinguished townsman, Prof. Hutson Ford, who is a sturdy advocate of operative interference. You have observed that he ALMOST INVARIABLY has had dangerous complications after his operations. And yet, he probably persists in the opinion that the operation of *Otis* is the thing. Gentlemen, no plan can claim infallibility for itself; no one method will cure all cases. The profession has not as yet compared the statistics of the new plan, for very few of its bad results have been placed on record. The future will determine its place on genito-urinary surgery. But I agree with Prof. Albert, of Innsbruck, Austria, when he emphatically declares, that *he has never seen any necessity whatsoever for operative interference,*

and relies solely upon continuous and occasional dilatation. Busch,* speaking of Reybard's and other urethrotomes, says: "The many instruments suggested by French surgeons suffer from the defects of *large calibre*, so that the stricture must possess a certain size, if their introduction be possible." * * * * "In fact, a stricture prepared for the introduction of such instruments renders the patient free from any urinary difficulties, and its further dilatation a matter of ease."

The "Deutsche Medezinische Wochenschrift," of Berlin, in reviewing my report of McCabe's case in the St. Louis "Clinical Record," suggests the introduction of metallic catheters, as followed by Dittel. I have made an effort to do so, but have found that they are too irritating, and offer no extraordinary advantages.

I shall close my lecture to-day by referring you to the very truthful words of Bryant:

"IN SEVERE AND NEGLECTED STRICTURES THIS PLAN IS ONE THAT OUGHT ALWAYS TO BE FOLLOWED WHEN POSSIBLE, AS IT IS SOUND IN ITS PRINCIPLE, SAFE IN ITS PRACTICE, AND AS EXPEDITIOUS AS IS CONSISTENT WITH THE OBJECT AIMED AT."

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, December 28th, 1882. The President, Dr. Tyson in the chair.

Tuberculosis of Spleen, Liver, and Kidneys.

Exhibited by Dr. Shakespeare.

These specimens were presented without a history of the case, and showed exuberant vegetations in pericarditis, abundant miliary tubercles of the pleura, of the liver, of the spleen, of the kidneys, and of the lymph glands in the region of the head of the pancreas. The subject came from the medical wards of the Philadelphia Hospital, and was last under your care, Mr. President, as visiting physician. They are brought to the notice of the Society mainly because the autopsy was made this p. m., and because many of the members have not had opportunities for examining such perfect examples of extensive and diffuse tuberculous infiltration without more serious involvement of the parenchyma of the lungs. Autopsy six hours after death, of C. J., colored, æt. 60. Diagnosis: Pericarditis and pleuritic effusion with strong bands of adhesions between parietal and visceral pleura. Thorax: Left pleural cavity completely obliterated by adhesions; right do. contained a large amount of straw-colored serum. The lobes of this lung were compressed against the spinal column, and were atelectatic. The lower lobe was firmly adherent to the diaphragm, and the three lobes were strongly united by adhesions. The parietal pleura was thickened, and everywhere studded with minute grey, semi-opaque miliary tubercles, the visceral pleura was in a similar condition, except that the tubercles were less numerous. The cut surface of the right

*Dr. Wilhelm Busch, Professor of Surgery and Director of the Surgical Clinic of Bonn, *Lehrbuch der Chirurgie*, Berlin, 1869, p. 340.

lung presented nothing abnormal save absence of air, but the sense of touch showed beneath and near the pleura a few scattered minute points, much smaller than millet seeds. The pleura of the left lung was also studded with numerous miliary tubercles, and the tissue of this lung was similar to that of the right. It was however crepitant. The pericardial sac contained $2\frac{1}{2}$ ounces of straw-colored serum. The whole heart was covered with an exuberant crop of vegetations. The cardiac walls were perhaps slightly softer than usual, otherwise normal. Abdomen: Peritoneum normal; no effusion. Liver slightly enlarged, with surface here and there raised by flat elevations, ranging in size from a hemp-seed to that of a hazelnut; capsule normal. The nodules were firm, and of a yellowish tint; the intervening tissue was a dark red. Section of the organ deeply, revealed similar nodules diffused through its substance, which seemed otherwise firm and normal. The spleen was slightly enlarged, firm, and extensively infiltrated with tubercles. The pancreas was normal, but the lymph glands near it were much enlarged, but neither softened nor caseous. No caseous focus was anywhere detected. The kidneys appeared normal, except for one or two more or less pyramidal yellow points. The case presents several points of interest: 1. Former history unknown. 2. Several aspirations removing considerable pleuritic fluid. 3. What was the origin of the numerous tubercular eruptions, and if there was auto-infection, what was its probable source? Dr. Tyson then gave a résumé of the ante-mortem history.*

Dr. Tyson said he regretted having to admit that he was less familiar with the history of the case than he should have been, since the patient was in his own wards in the Philadelphia Hospital. He had been previously thoroughly studied by Dr. Bruen, whose absence he regretted, as Dr. Bruen knew so much more about the case. The man had, however, been more than once tapped. He was a colored sailor, aged 60 years. When Dr. Tyson took charge of the ward, in September, the man presented the physical signs of double pleuritic effusion, orthopnea, or feeble transmitted heart sounds, but no cardiac murmur. There was oedema of the legs. He was tapped with great benefit, and under a restorative treatment he rapidly improved, so that he soon became one of the walking cases in the ward, attracting little attention. About December 1 he became very much worse. The orthopnea and other signs of accumulating fluids returned, and so did the oedema of the legs. His urine was repeatedly examined for albumen, with negative results. He was tapped upon the right side, and three pints of fluid removed, with but partial relief. The other side was also aspirated without success. A cardiac friction sound was noted, which seemed to be pleuro-pericardial, but in the light of the autopsy it was probably pericardial. He died on the 13th of December. With reference to the case cited by Dr. Formad, it had also seemed to be a simple plastic pleurisy, with feeble, distant heart sounds, with no murmurs, occurring

in a case where, after prolonged illness, death resulted from exhaustion. Dr. Tyson had never seen such extensive new formations resulting from serous inflammation, the large lymphoid masses in the abdomen having at first suggested the idea of malignant disease. The patient had a distinctly scrofulous history. The father had died after pleurisy, with cheesy deposits, followed by miliary tubercles of the lungs later in life. Four or five uncles and one aunt had all died phthisical at from between 20 and 30 years of age.

Dr. Bartholow asked if the range of temperature accorded with that usually found in phthisical cases.

Dr. Tyson said that in the case related by Dr. Formad the temperature was seldom, if ever, above 101° ; mostly below this point. In the case reported by Dr. Shakespeare, he was unacquainted with the temperature record.

Dr. Nancrede demurred to the view that repeated tapping had any causative relation to the development of tubercle after pleurisy, but thought that the chronicity of the affection and altered condition of the pleural sac, which demanded frequent operations, were the real explanation of the alleged fact.

Dr. Musser said that a relationship between pleurisy and pulmonary tuberculosis could not be denied, but whether the pleurisy or the tuberculosis be antecedent was difficult of solution. That the former is primary may be inferred from the fact that persons are considered as threatened with phthisis who have subclavian arterial murmurs due to the pressure or pulling on the artery of organized lymph. Likewise are the various friction sounds and exocardial murmurs noted to precede tuberculosis, and especially to occur in those tuberculously predisposed. Examples of both cases have come under his observation. It seems to him that a primary acute pleurisy is a rarity, occurring in a non-tubercular subject. The last series of cases of what would be called primary pleurisy he had seen were in persons predisposed to tubercle, and in some of the cases tubercle subsequently developed. In short, so-called primary plastic pleurisy occurs only in tuberculously disposed individuals; other forms are secondary to some other process, as Bright's disease, septicæmia, etc. Trousseau calls attention to latent pleurisy with effusion as being often an expression of a tuberculous diathesis, while also a latent pleurisy may occasion development of that diathesis. Two cases illustrating these views have lately come under his notice.

Dr. O'Hara said that although he had not had much experience with latent pleurisy, he recalled a case of a young man seen five years ago, where extensive effusion into one side of the chest had unsuspectingly occurred, and when detected had been removed by tapping. Apparent recovery then ensued, to be followed in a few weeks by copious effusion into the other pleural cavity. Tapping was again resorted to, the effusion never recurred, and the patient remains healthy and free from tubercle at the present time. He would like to ask if when the term "all the serous membranes were affected" was used, those of the brain were included.

Dr. Tyson replied that there had been no head

*Dr. Formad here related a case of general tuberculosis, and showed the specimen, but no notes having been forwarded to the recorder, any fuller account than the remarks of Dr. Tyson is impossible.

symptoms in the sailor's case. In that mentioned by Dr. Formad, decided mental aberration, demanding watchful restraint, had been present. No inflammation of the meninges had been found, the only disease consisting of a small tubercle starting from the pia mater and dipping down into the brain substance.

Dr. Shakespeare closed the debate by referring to the causes of tuberculosis in general, and its mode of diffusion through the organism. He called attention to the failure in discovering any caseous focus, while admitting the possibility of such, if minute, escaping the most painstaking search. In this and similar cases, all that could be safely said was that the *caseous point was not found*. Assuming, for illustration, that the point in the kidney might have been the origin of the auto-infection in this case, he referred to the communication between the left renal vein and the inferior mesenteric vein, and the direct communication with the portal system thus effected. As to the point raised by Dr. Musser, he believed in plastic pleurisies distinct from tuberculosis. He had examined very many microscopic sections of pleuritic adhesions, and very many had proved to be free from tubercle. Authors who have made original investigations on man and the lower animals have also as distinctly recognized a plastic pleurisy without tubercle, as they have one associated with this formation. He thought tapping in a person not predisposed to tubercle was no more likely to produce this disease than tapping an anasarctous limb. He was well aware of the facts dwelt upon by Drs. Musser and Formad, viz: the association of tapping with tuberculosis and plastic pleurisy with tuberculosis—but he believed the frequency of this association had been exaggerated. He thought that in view of the well-grounded belief that in certain classes of animals, as well as in certain families of men, inflammation tends to linger, to produce accumulations, which are prone to degeneration, and to excite local or general tuberculosis, it is more logical to conclude that in such cases as above mentioned there is at the outset a tainted constitution—a soil already sowed with the dormant seeds of disease waiting to be awakened to their active processes of destruction by the stimulation of an exciting cause. The more frequent the action of the exciting cause, the more certain is this dormant tendency to be aroused.

[Dr. Shakespeare then proceeded to combat the views advocated by Dr. Formad in this debate. Owing to their non-reception by the Recorder, Dr. Shakespeare's remarks are also of necessity omitted.]

Two Cases of Carcinoma of the Stomach.

Exhibited by J. H. Musser.

Case I. Scirrhus of the pylorus; general proliferation of the connective tissue; interstitial nephritis. Malignant disease of the pylorus and of the lesser curvature of the stomach was diagnosed when the patient applied at the Medical Dispensary of the University Hospital May 14, 1882, for treatment, on account of the physical signs especially; and of some points in the clinical history. Palpation and percussion revealed a firm, non-pulsatile, immovable, slightly painful tumor in the middle of the epigastric region, one

inch to the left of the median line, about the size of a turkey-egg. When lying down, the abdomen was slightly scaphoid, but the left upper quarter was distended. A curved line extending downwards from the umbilicus to the flanks represented the lower limit of this swelling, which was soft and resistant, tympanitic on percussion, and with care could be discerned as starting from the hard tumor in the epigastrium. In short, it was due to a distended stomach. Although the tumor was not in the position of the pylorus, and although the patient had never vomited, yet pyloric disease was determined upon because of the gastric distention. On account of the absence of marked obstruction, the position and occurrence of pain in the lumbar region, disease of the lesser curvature and the posterior wall was decided upon. The autopsy revealed that the malignant growth surrounded the stomach at the pyloric end, but being greater in extent in the lesser curvature. An adhesion to the left lobe of the liver explained the position of the tumor. The patient first noticed the localization of the disease in November, 1881, by the occurrence of pain in the epigastrium following a jar. She noticed that her health had failed three months before, and that menstruation had ceased six months previous to the epigastric pain. Note here the failure of health before any local evidences of disease, not even dyspeptic symptoms. She was a widow, æt. 40 years, with one child; her health had always been very good, her circumstances moderate, and her habits exemplary. In addition to a constant burning pain increased by food, her appetite was poor, tongue pale, with large papillæ; flatulency was marked, and the bowels constipated. She presented a sallow cachectic appearance, was somewhat emaciated, extremely anæmic, with cardiac, arterial and venous blood-murmurs, and accentuated second-sound. She was under observation until her death, October 17, 1882.

The pain and constipation were relieved by treatment, but the course was only downwards. In addition I may note the cachexia became more marked and the classical appearance of the face was wonderfully depicted—transverse and vertical lines on the forehead and semicircular lines around the mouth from the ale of the nose to the chin, and vertical lines on the chin and lower lip. The hue of the countenance changed—growing darker and darker. This peculiar hue of the face Dr. Musser considered the most reliable symptom of approaching dissolution. It was noted one month before death. During the last two months of her illness she suffered much from soreness of the mouth and tongue, without visible lesions; from burning in the fauces; difficulty of deglutition; acidity; vomiting taking place every third or fourth day of a clear acid fluid, coagulated milk bile-stained, and "coffee-ground material." A painless, watery diarrhœa occurred frequently, with tarry masses. Œdema of the feet and ankles took place six weeks before death. The tumor grew in size and changed position, falling downwards. Three days before death it was noted to pulsate, was tender, and was three inches long, extending from the median line to the left on a level with the umbilicus. Autopsy 12 hours after death. Extreme emaciation; rigor mortis marked; œdema of feet. Heart slightly

enlarged, the left ventricle walls $8\frac{3}{4}$ lines in thickness; heart weighed 7 oz. Aorta 1 inch $1\frac{3}{4}$ lines in diameter, and slightly atheromatous. Deposits of fat along the septum were noted, and the muscular tissue itself was fatty. The stomach was in the position defined a few days before death, was greatly dilated, with the disease at the pyloric end extending along the lesser curvature four, along the greater curvature two inches, and completely encircling the organ. The stomach walls became thickened, with much hypertrophied muscular coat as they approached the diseased area. The internal surface of the tumor was flat, elliptical, and defined by an everted lip of varying thickness about four lines high. The surface was uneven, some nodules being half an thick. The most central portion presented distinct evidences of ulceration.

The liver was rather larger than normal, and seemed fatty, and was not indurated. The kidneys were small, hard, and the capsule peeled off with difficulty. Microscopic examination of the stomach, liver and kidneys, Dr. W. E. Hughes assisting, showed abundant irregularly shaped epithelial cells packed closely in a fibrous stroma, but slightly developed in, and containing numerous nuclei. Liver-cells fatty and pigmented. Proliferation of the connective tissue around the hepatic and portal veins was noted; many nuclei proving its recent origin. The kidney was markedly cirrhotic, the connective tissue being *not* of recent formation. Note the general proliferation of connective tissue in the organs. No albumen was detected during life in the urine, nor were any renal symptoms noted, yet there was no doubt interstitial nephritis belonging to the variety described by Gall, Sutton and Mahomed. The mal-assimilation consequent upon the gastric lesion was the predisposing factor in the production of this general change.

Case II. Scirrhus of the pylorus; symptoms simulating idiopathic anæmia. F. R., æt. 54. White, German. Resident of a healthy, locality but much exposed as lumberman during the winter. Addicted to constant use of spirits, malt liquors, and tobacco. Had a fever of six weeks duration at the age of sixteen years, and eight years ago some pulmonary inflammation. Never had malaria or syphilis. Does not know cause of mother's death; seven brothers and sisters healthy; father died of old age; his own three children living and healthy. Admitted to University Hospital, December 20, 1878. During the previous winter had numerous gastric attacks as shown by pain and loss of appetite. In the spring and summer he lost flesh and strength, and was subject to pain in the bowels and in the hepatic area, flatulence, pyrosis and constipation, but never vomiting. On account of salivation in June, he became especially debilitated. At time of admission, weight 118 pounds, usual weight 170. Lies on left side perfectly apathetic, with the physical and mental processes slow of action. Extremities cold, very anæmic, conjunctiva and mucous membrane very pale; sclerotics pearly white; complexion of a sallow, dirty hue. Palpitation of the heart, dyspnoea and subjection ear noises were noted. Temperature irregular. Appetite poor, flatulence, and pyrosis, pain and tenderness in epigastrium; no definable tumor,

but a sense of induration. Hepatic and splenic areas of dullness normal. No venous hum. Heart sounds weak; urine sp. gr. 1018, neutral reaction, albumen one-sixth. No casts, bile or sugar; phosphates not in excess. Blood—white corpuscles in excess, red greatly decreased in number. Ophthalmoscopic examination; slight retinitis, O. D. pallid; central artery dilated. Venous blood paler than usual. Absorption of choroidal epithelium, allowing choroidal circulation to be seen. Macula healthy; no hemorrhage throughout fundus. Both eyes present the same appearances. A low typhoid state soon developed with diarrhoea and excessive flatulence. For three days prior to death, vomiting occurred. He died December 30, 1882. Autopsy. Stomach alone examined. It is to be regretted that the full record was lost. Stomach adherent to liver and transverse colon. Lesser curvature from pylorus half way to cardiac orifice, infiltrated with cancer, extending two inches over the anterior wall and at the pylorus encircling the organ. Pancreatic and biliary ducts pervious. Microscopically, the growth was found to be scirrhus carcinoma.

Remarks.—On account of the profound anæmia and the absence of tumor and vomiting, idiopathic anæmia was considered. The examination of the blood and the condition of the eye ground, contra-indicated such a diagnosis. The normal size of the liver and spleen and the non-glandular involvement excluded leucocythæmia. It is to be regretted that the exact numerical blood count was not recorded. In this case the lesser curvature was very much involved and a distinct tumor was absent; quite the opposite of case I.

Tumor of Brain.

Presented by Dr. A. P. Brubaker, for Dr. H. Leaman.

John Jones, æt. 53, laborer. When first seen, the patient was lying on his back, with head drawn backwards into the pillow, and complaining of stiffness and soreness in back of the neck. The mouth was widely opened and parched, and the breathing deep and heavy. He was in a semi-unconscious condition, from which however he could easily be aroused; but soon relapsed into his former state, which was attended by stertorous breathing. Speech and deglutition were both interfered with, but not abolished. There was involuntary passage of urine, but the bowels were constipated. Venereal ideas were excessive, but accompanied by complete impotence. Voluntary movements of the extremities and also the power of co-ordination were considerably impaired. Pulse and temperature were normal. Liquid food was taken with difficulty. His condition had been as described four days previous to my first visit, on September 4, 1882. The symptoms gradually increased, and coma supervened, which ended in death September 17, 1882. Following history was obtained from the family: Twenty-six years ago the patient was confined to bed with "nervousness" for a period of two years, when he passed a calculus about the size of a date seed; again, a month later, another smaller one passed. His bladder continued to give him more or less trouble up to death. He had his clavicle broken nineteen years ago, but there was no injury to the

head. About sixteen years ago he was suddenly seized while at work with a severe headache, and became totally blind, which lasted for twenty-four hours. This was relieved by wet cups to back of the neck. From that time he was subject to what they called "shaking spells"—when standing there would be a violent trembling of the knees and shaking of the arms. These attacks occurred about once a month, and occasionally three or four times a day. They increased from year to year in frequency and severity, and appeared to be excited by high winds and storms. In February, 1882, he was seized with paralysis, beginning in the left little finger, thence gradually extending to the ring and middle fingers, until the hand became powerless, but was able to move his arm. Then followed a numbness in the outer side of the left side, attended by impairment of the power of co-ordination, so that on attempting to walk he was compelled to run to keep from falling. He frequently fell in the street, and had to be carried home. Last February loss of speech supervened, which lasted for one month; the patient then began to speak in monosyllables, after which speech gradually returned. Autopsy: Congestion of the entire brain. By removing it four or five ounces of serum ran from the cranial cavity. Brain substance seemed to be normal throughout. In the right fissure of Sylvius was embedded a tumor about an inch and a half in diameter, which was almost entirely concealed from view by the convolutions. It rested upon the convolutions of the island of Reil, completely disorganizing them. The inferior extremities of the ascending frontal and parietal convolutions were normal. The upper surface of the temporo-sphenoidal lobe was somewhat disorganized. The tumor apparently sprang from the pia mater.

Report of the Committee on Morbid Growths: A section made from the tumor presented by Dr. Brubaker, and examined microscopically, showed that the growth was tubercular. Its histological structure is seen to consist of fibrous tissue constituting a reticulum, the meshes of which are filled with lymphoid cells. These appearances are very distinct at the peripheral zone of the tumor, while the centre and inner zone are in a state of retrograde metamorphosis, presenting a very granular appearance, scarcely stained by the carmine. The blood vessels are mostly obliterated; their lumen being filled with coagulated blood or granular debris." December 28th, 1882.

Enlarged Lymphatic Glands.

Exhibited by Dr. W. H. Parrish.

I show five lymphatic glands removed from the axilla of a patient whose breast I amputated about nine months ago. The case was then reported at the Obstetrical Society. The specimen was referred to a committee, and Dr. Beates made a microscopical examination, and concluded that the growth was an adenoma that had undergone carcinomatous change. Of the enlarged glands presented this evening, three, about the size of an almond, were removed from the axilla—a fourth, of smaller size, from just below the clavicle, and the fifth from the side of the neck, about an inch from the clavicle. The patient presents no cachexia. (The specimens were referred to the Committee on Morbid Growths.)

Polypi from the Uterine Cervix.

Exhibited by Dr. W. H. Parrish.

I also present this evening two small growths, each about the size of the last phalanx of the thumb, removed to-day with a wire écaraseur. On Christmas evening I saw for the first time a patient of French birth, a teacher, apparently about 35 years old. When I entered her room she was in a stated of syncope from hemorrhage from the genitals. The hemorrhage had, however, ceased. With the application of hot wet cloths over the front of the chest, and by hypodermic injections of whisky and aromatic spirits of ammonia, she in a few minutes revived, so as to be able to tell me that she had not menstruated for three months, when suddenly bleeding began from the womb, and continued during the day, with an exacerbation just before sending for me. As the patient's condition was evidently a critical one, I asked the direct question, if she had not had, or was not having, an abortion? She said it was impossible. I then learned that she was single and 42 years old. A digital examination showed an intact hymen, and a substance in the vagina that at first touch felt very like an embryo of about 3 months. But I soon recognized that it was a growth attached to the lower part of the cervical canal, and that there was another distending the cervical canal. The latter felt still more like an embryo or ovum, and, in fact, in the absence of the one in the vagina might have at first misled me into thinking that the patient was aborting. Slight traction on it soon showed that it was attached. There was no return of the bleeding, and to-day, with the assistance of Dr. M. O'Hara, I removed both the growths with the wire, and without etherization or the use of a speculum. A remarkable feature of the patient's history is that she had always menstruated scantily, and at intervals of five to six weeks. Never before had she evinced a tendency to uterine hemorrhage. I am confident that the patient was not pregnant. I presume that, being virginal, she is approaching the menopause.

Frozen Sections.

We understand that the professors of anatomy in the Royal College of Surgeons in Ireland (Professors Thornley, Stoker and Cunningham) have taken advantage of the severe weather which we have lately had, and made a large number of sections of the frozen human body. Collecting a large quantity of snow, they subjected three bodies to the freezing process, and from these they have obtained nearly 150 sections of different regions.

The Next International Medical Congress.

We are officially informed that according to the desire expressed by the International Medical Congress, at its seventh session, in London, 1881, and in consequence of later discussions on this subject, it has been resolved that the eighth session of the Congress shall be held in Copenhagen.

In order to prevent collisions with other medical congresses, it is announced thus early that the eighth session of the International Medical Congress will take place in Copenhagen during the days from the 10th to the 16th of August, 1884.

EDITORIAL DEPARTMENT.

PERISCOPE.

The Expectant Treatment in Surgery.

H. I. Raymond, M. D., *Med. News*, Dec. 30, 1882, is of the opinion that in wounds of the chest, the bullet itself may prove innocuous, and may have carried no foreign body in with it that may cause septic or purulent infection. This he believes to be the rule, the contrary the exception.

"It is manifest, therefore, that the prime factor in treatment of such wounds is to hermetically seal them by antiseptic occlusion, that no infection may take place in the wound non-infected when it comes into the hands of the surgeon. Strange enough, it was the habit in Bellevue Hospital to occlude antiseptically a wound of the chest, but to probe and introduce drainage-tubes into a gunshot wound of the soft parts. But why should we fear to occlude a bullet wound of the biceps muscle, when it is his practice to hermetically seal up a bullet wound of the chest, and that too with good results?"

Of seven cases of penetrating gunshot wounds of chest, in Bellevue, treated by antiseptic occlusion, but one case died, the others making perfect recoveries.

The doctor takes exception to the statement "that penetrating gunshot wounds of the joints are invariably attended with suppuration." The fallacy of this statement is most certainly pointed out by twenty-seven tabulated cases in the experience of Karl Reyher, two-thirds of which were treated by primary antiseptic occlusion, and one-third by primary antiseptic drainage, and also by six other cases of the same nature treated by primary occlusion, not even antiseptic.

Karl Reyher had under his care twenty-seven penetrating gunshot wounds of the joints; eighteen of these he treated by primary antiseptic occlusion, "this is, by hermetically sealing the mouth of the wound by an antiseptic covering, without having previously introduced probe or finger or drainage-tube into it;" of these eighteen but one death occurred. The remaining nine cases were treated by primary antiseptic drainage, and of these two died.

"That is to say, of twice the number of cases of penetrating gun-shot injuries of the joints treated by primary antiseptic occlusion, but 50 per cent. of deaths resulted as compared with the mortality of half that number of cases treated by primary antiseptic drainage," recommended as being the best method of treatment adapted to such wounds.

"Add to this result six cases of penetrating gun-shot wounds of the joints, treated by primary occlusion, even *not-antiseptic*, in all of which cases there was lodgment of the projectile, and recovery with no resulting ankylosis, and in the face of these stern facts, the announcement that penetrating gun-shot wounds of the joints are invariably attended with suppuration, is startling."

The following are the conclusions with which the article is summed up:

1. That this method of treatment is applicable to a large percentage of wounds inflicted by a cartridge from a revolver, or cylindro-conoidal bullet from a modern rifle or carbine.

2. That in properly-selected cases, wounds treated by this method do not suppurate or secrete any septic fluid.

3. On the contrary, this immediate antiseptic occlusion is intended to forestall suppuration, to prevent the accession of inflammation, and to allow a reparative reaction and secretion to be set up.

4. That the simplicity of this method should recommend itself to the profession in the treatment of wounds to which it is applicable.

Hunterian Chancre of the Lip.

Dr. John Taylor reports the following case in the *Glasgow Medical Journal*:

Marion G., aged 19 years, residing at Caledonia Road, consulted me on the 2d of June, 1882, regarding a sore on her lower lip of some ten days' duration. It was covered by a yellow scab, felt indurated and somewhat elevated, was about the size of a threepenny piece, and, together with its hard surroundings, felt in the substance of the lip like a field bean. It had, I was told, resisted such applications as lip salves and preparations of borax. On palpating in the submaxillary regions, I discovered swelling of the glands there and behind the angles of the jaws; these facts, together with her occupation—*puella publica*—led me to recognize the sore as specific. She was at once placed upon a course of red iodide of mercury, and for a local application I dressed the chancre with lint soaked in black wash and secured in position by a split cloth tied behind the neck and over the head after the manner for fractured or dislocated maxilla. In the course of a few days I was called to see her, owing to the onset of great pain in the scalp; on examination I found the tissues over one parietal bone extremely tender and a little tumid. I diagnosed the complication as one of acute pericranitis, and began treatment by the application of a few leeches, most of which, however, declined the treat, being either disgusted by the amount of hair perfumery or not finding her flesh sufficiently savory, so I had to content myself with the amount sucked by one fellow less reluctant than the others, and from whom, when once firmly attached, I snipped the tail, and holding a tumbler beneath him, obtained, drop by drop, a discharge equivalent to the engorgement of two or three leeches. The patient then had sleep obtained at nights by chloral draughts, and in the daytime continued her mercurial, to which large doses of iodide of potassium had in the meanwhile been added; to these measures, after a time, both the periostitis yielded, and the sore, losing its hardness, healed up. But only lately again she has come under my notice for the cure of secondary symptoms in the shape of a measly rash on her chest, and for sore throat and considerable aphonia. The case now, of

course, resembles one in the ordinary run of syphilitic examples.

Primary syphilis, resulting as it does from the application of the virus to the natural points of contact of one individual with another, makes its appearance on the genitals, or more rarely in the case of the nurse on the nipples, and rarely is seen in our country on any other site; but in France it appears, I find, on consulting Allingham's work on "Diseases of the Rectum," to be often seen not only on the lip, but also on the anal verge. As far as the lip cases are concerned, probably it may be got by using the same pipe or culinary articles as one affected with mucous plaques or specific sore throat; but, in the case I have just described, the unfortunate girl acquired the disease by the direct insertion and unnatural application of the penis to the part.

Tetanus from a Carious Tooth.

The *American Journal of Dental Science* says that a very remarkable case of fatal tetanus, ascribed to the irritation of a carious tooth, was reported some time back in one of the West of England journals. The patient was a shoemaker, residing at Bridgewater, who had enjoyed excellent health until he was seized with violent pain in the side of his head. He was treated in the first instance by a chemist for neuralgia, but the symptoms becoming aggravated, Mr. Kemmis, a medical practitioner, was called in. He found the patient insensible, with his jaw locked and immovable. Treatment, however, was unavailing; the man remained insensible, and died in a few hours. At the inquest Mr. Kemmis stated it as his opinion that death was due to tetanus brought about by a decayed tooth, and he characterized the case as a most extraordinary one—a statement with which every one will agree. Simple trismus from some form of dental irritation, generally the difficult eruption of wisdom teeth, is not a very rare phenomenon, and cases of it will be found recorded in several of our back numbers. But general and fatal tetanus from a similar cause is happily of extremely rare occurrence. Mr. Tomes has recorded a case which was apparently due to the operation of pivoting, and Wedl has mentioned one in which tetanus followed the extraction of a tooth. In Mr. Tomes' case, as in the one the particulars of which are given above, death occurred very soon after the first appearance of muscular spasm.

Extract of Stigmata of Maize.

The anæsthetic and diuretic action of the stigmata of maize was recognized in 1879. M. Ducasse has recently experimented largely with an extract of the stigmata and a syrup prepared with it.

At the dose of 22 grains he finds that the extract has a calming influence on the pain of chronic cystitis, gravel, and nephritic colic, at the same time aiding in the expulsion of gravel.

This anæsthetic action is very marked, especially in nephritic colic, where it calms the pain when morphine injections have proven ineffectual; its action is followed by micturition, the urine carrying away with it a large proportion of gravel.

If the medicament be continued for a period, the

accidents rarely return. It is, in a word, the best preventive of gravel and nephritic colic.

In acute cystitis, this anæsthetic action is nil, in all probability because there is an inflammatory element present which prevents the action of the medicament on the mucous membrane of the bladder.

As regards the diuretic action of stigmata of maize, M. Landrieux, of the Paris hospitals, arrived at the following conclusions:

1. The diverse preparations of these stigmata act not only as a modifying agent on the urinary organs; they have also incontestably a distinct diuretic action.

2. Diuresis is rapidly obtained; after three or four days, the augmentation in the quantity of urine is distinct and considerable.

3. These diuretic effects are observed not only in diseases of the urinary organs, but also in those affecting the circulation (diseases of the heart and vessels).

4. The pulse becomes regular, arterial tension augments, while venous tension diminishes.

5. The medicament has no perturbing action, either on the nervous system or on the digestive functions.

6. As the drug is very well tolerated, its use may be continued in chronic diseases a month, six weeks, or even longer, without inconvenience.

Removal of a Gangrenous Testicle.

Dr. Paul T. Tupper reports the following case in the *St. Louis Courier of Medicine* for December, 1882:

Thomas C., born in Ireland, aged 60, married, laborer. Entered hospital September 30.

History.—General health has been good. In 1863, was ruptured by heavy lifting. The rupture was at first very small, but gradually increased in size until it filled scrotum. Trusses seemed to prove inefficient in keeping hernia reduced. Frequently had great difficulty and pain in returning intestine to abdominal cavity. Right testicle has remained somewhat larger than the other ever since the receipt of a kick in the scrotum many years ago. At the time of the injury the testis was greatly enlarged and inflamed.

About two weeks before entering hospital, testicle again became enlarged and painful, but this time without any apparent cause. The hernia was reduced the day before entering.

Condition on Entering.—The right testis was greatly enlarged, globular and painful. The scrotum was tightly drawn over the rounded mass. Physical examination gave no clue to the true state of affairs within. Hernia reduced.

Operation.—Sept. 30th, ether. An exploratory incision was made by Dr. Gregory through the scrotum into the substance of the testicle, disclosing gangrene of the entire organ. The odor was most offensive. Incision was enlarged and the testis enucleated—the cord being so rotten as to be easily detached without the use of the knife. The old hernial sac was discovered in place, and greatly thickened, but containing no loop of intestine—this having been recently reduced. The finger could be readily introduced through the sac and inguinal canal into the abdominal cavity. The parts in the scrotum were so changed by the

morbid processes as to be almost unrecognizable; but what was supposed to be a portion of the omentum was found unreduced, and lying *posterior to and almost entirely surrounding the destroyed testicle*, the whole being tightly bound down by inflammatory adhesions. This strange condition could only have been produced by a rupture of the hernial sac posteriorly, allowing an escape of the omentum into the scrotal cavity. This supposition is supported by the fact that the finger could be passed up as far as the abdomen *between the sac and omentum*.

A single ligature was cast around the cord and the accompanying vessels. The hernial sac was occluded high up by transfixing and ligating on either side. Parts washed out with a 1 to 8 solution of carbolic acid. Dressed with lint steeped in weak carbolized solution. October 27, discharged well.

Syphilitic Enlargement of Tonsils.

In the *Deutsche Medical Zeitung*, No. 45, is to be found an abstract of the conclusions of Dr. Paul Hamonic on this subject.

He distinguishes, during the secondary stage of syphilis—1. *Simple hypertrophy*, which is analogous to the swelling of lymphatic glands, is tardy in its development, and, as it occasions no symptoms, is often overlooked. Both tonsils are almost always affected, though to a different degree. The enlargement takes place forwards, bulging the anterior pillar of the fauces, and rarely gives rise to deafness. The tonsils are hard and somewhat elastic; the normal depressions on their surfaces are exaggerated. The uvula tends to go over to the larger tonsil. Sometimes the tonsil may be reduced in size by anti-syphilitic treatment. 2. *Hypertrophy associated with angina*. In this there is not so much fever as in ordinary acute angina; the duration is variable, and relapses are very liable to happen. 3. *Hypertrophy complicated with syphilides*. Most frequently the syphilide appears on the tonsil and the anterior pillar of the fauces. When syphilis affects a previously serofulous tonsil the enlargement is very great, of pale color, often spongy and with large crypts; there is considerable pain, the voice becomes nasal, and the hearing, taste, and smell are altered. The course is generally chronic, and there is a great tendency to recurrence. Ordinary tonsillitis and sore throat may supervene even when the tonsils are syphilitically enlarged, but then, though peritonsillar suppuration may occur, it would appear that the tonsil itself never suppurates. Hamonic states that there is no objection to excision of the syphilitic tonsils if they be very large.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—The value of hot water injections in uterine diseases is set forth by Dr. P. V. Schenck, of St. Louis, in a recent reprint. He gives careful directions for their employment.

—Dr. John Godfrey, in his Anniversary Ad-

dress before the New Orleans Medical and Surgical Association (reprint), drops into poetry, and discusses in rhyme and reason about medicine and medicine men.

—The address in surgery before the American Medical Association, was by Dr. William A. Byrd, of Quincy, Ills., and upon excising portions of the alimentary canal covered by peritoneum. It has now appeared as a reprint, and is a valuable contribution to surgical literature.

BOOK NOTICES.

A Guide to the Practical Examination of the Urine.

By James Tyson, M. D. Fourth edition. P. Blakiston, Son & Co., Phila.

Dr. Tyson's manual is one of the most complete on the subject of which it treats, and this fourth edition has been carefully revised and completed in all points where it was required. It contains a number of colored plates and wood engravings, among them an accurate reproduction of Vogel's scale of urine tints.

A Compend of Human Physiology. By Albert P.

Brubaker, M. D. P. Blakiston & Son, Phila. Pp., 133.

This is No. 4 of the "Quiz Compend," a series of small volumes intended for the use of students, to prepare for their examinations. It is well adapted for the purpose, except in the size of the type, which is entirely too small for a book intended to be closely studied.

The Hospital Treatment of Diseases of the Heart

and Lungs. By Charles H. Goodwin, M. D., New York. Published by the author. Price \$1.50.

The writer of this volume presents a series of notes on the treatment of thoracic diseases as exemplified in the various hospitals of New York city. Most of the leading hospital physicians are represented, and the notes appear to be carefully recorded.

No doubt many useful suggestions can be obtained from its pages. There is, however, a considerable difference between the class of cases and the forms of disease as seen in the wards of a hospital of a great city, and those of country homes and of citizens of the better class. This difference should not be forgotten in applying the knowledge contained in the work before us, and others of its class.

—A goat farm has recently been established in England for the purpose of supplying goat's milk to London infants and invalids.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D.,) EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D..

115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

HOW THE U. S. PHARMACOPEIA WAS PUBLISHED.

General and apparently well-grounded indignation has been felt by both pharmacists and physicians at the manner in which the "United States Pharmacopeia" has been published.

It would appear that the sub-committee, who had charge of obtaining a publisher and arranging about the royalty and copyright, either acted in a discredibly negligent manner, or else did not respect the instructions given them.

The publishers whom the committee selected from the six houses who put in bids, were William Wood & Co., of New York city. Their offer was 10 per cent. on the retail price. Other houses, equally energetic and responsible, offered 15, 20, 26, 34, and even 41 per cent.

Moreover, the Pharmacopeia Convention of 1880 instructed the Committee of Revision to contract that the book should be sold "through the ordinary trade channels." In the contract with Wood & Co., this phrase was omitted, and in its place it was merely stipulated that the market should be fully supplied. The purpose of this change would seem to be that the book could be retained within the agencies of that publishing house.

It is easy to see that the sub-committee in making this contract not only disregarded their instructions, but that they sacrificed the interests of the Association for which they were acting.

Did they do this through stupidity and ignorance of business usages, or through motives and under influences still less creditable?

They have not yet answered these questions, although the results of their bargainings have been made public for some time.

The names of the sub-committee were Drs. Robert Amory, E. L. Wood, Thos. Doliber, of Boston; Dr. H. G. Piffard, New York; Dr. W. S. W. Ruschenberger, Philadelphia.

Another statement remains to be made in this relation. We understand from pharmaceutical sources that the committee, or Wood & Co., or both, intend to construe the copyright claim on the Pharmacopeia with extreme rigidity. Works publishing extracts or formulas from it will be

pursued legally if there is the faintest chance of convicting them of breach of copyright.

In whose interest is this to be done? Certainly the Committee have not shown that regard for the welfare of the Association, that we can attribute this motive to them. It is moreover not to the benefit of science that such rigid construction of the copyright law should be observed.

We should like to have some of that Committee offer a solution of their actions.

THE DISPOSAL OF THE DEAD.

This should be a subject uppermost in the minds of all medical men who are physicians in every sense of the term, not alone to cure disease, but to prevent it. The expediency, not to say necessity, of some improved mode of disposing of our dead, becomes every day more pressing.

Edward Garraway, in the *British Med. Journal*, December 23, 1882, presents the subject in a few concise words: "The evils of earth-burial, and its prospective dangers to the community, are admitted; and since Sir Henry Thompson's celebrated pamphlet, the objections to cremation—physical, moral, and religious—have been refuted again and again, and the question now resolves itself simply into a matter of sentiment. In these days of æstheticism, it is surprising that the mind does not revolt at the contemplation of the state to which the shrine of those we love attains but a few days after death, and so continues for months and years—an object of loathing and disgust.

"But we are accustomed to it: and to cremation, with its purification by fire, its true rendering of ashes to ashes, we are not accustomed. The people must be educated, though probably it will be long before the masses can be persuaded to relinquish the privilege they seem so highly to esteem—the privilege to rot."

ENDOWMENTS.

A great deal has been lately done in this line, but much more ought to be done.

A system of education whereby the teachers are dependent upon fees for their remuneration can never hope to approach that perfection of instruc-

tion that ought to be found in our first-class institutions. To a practical mind, this proposition is obvious.

Since the acquirement of money is an instinct, we might say, of human nature, in some to a greater, and in others to a lesser degree, but in nearly all to some extent, it follows as a logical sequence that the system that makes remuneration dependent upon fees, and consequently upon the number of pupils, cannot possibly be as satisfactory as that which assures the instructor a fixed and liberal income, irrespective of the number of pupils.

The quantity would not be so great, but the quality would be infinitely finer.

Our oldest institutions are gradually approaching this Mecca, and the standard of education is proportionately higher.

There is, however, one great void in existing endowments, one that calls imperatively, with a daily increasing force, and one that cannot or at least *ought* not to be neglected.

We require badly a chair of Hygiene, in some first-class medical institution; its great practical value is coming to be recognized daily more and more, yet its teaching is relegated to our auxiliary courses, which but few medical students attend.

We have some rich men in our profession. Let some one, or several of them, erect an immortal monument to his or their memory, by giving the money requisite to endow such a chair. If the necessary cash is forthcoming, the authorities will be very willing to establish the chair.

THE PROTECTION OF THE INSANE AND THE PREVENTION OF INSANITY.

Of all philanthropic labors, surely that which has for its object the protection of those who, on account of infirmity, are incapable of protecting themselves, stands pre-eminent.

No more praiseworthy object can be conceived, and it deserves the hearty co-operation and support of all intelligent persons.

It is therefore with much pleasure that we refer to the recent meeting of the "National Association for the Protection of the Insane and the Prevention of Insanity," which held its annual

meeting in the hall of the College of Physicians in this city on last Thursday.

The most not edrepresentatives of our profession, at well as distinguished citizens generally, and prominent gentlemen from various sections of the country, were in attendance.

In our next issue, we will give a report of the proceedings.

THE NATIONAL BOARD OF HEALTH.

The Board of Health of West Virginia has passed a series of resolutions in which they request the Senators and Representatives of West Virginia in Congress to use their efforts to have the present laws, that so hampert he effectual working of the National Board, rescinded.

With but one or two exceptions, the various State Boards, as well as the American Public Health Association, seem to be in perfect accord and harmony with the National Board of Health ; and where there is found so much unanimity, there must be a good cause for it.

We feel, therefore, inclined to side with the National Board, and to add our appeal to Congress to give them a fair show ; and at the same time to whisper in the ear of our reform Governor, *that we need a State Board of Health.*

TEMPORARY INSANITY.

The North Carolina *Medical Journal* speaks of the case of a man who, on account of his sister's disgrace, murdered her. He was tried, and declared, upon examination, to have been insane when he committed the deed, and afterwards sent to the State Insane asylum. Two years have elapsed and he is now pronounced *sane*, is liberated, and goes "scot free."

We take sides with that esteemed journal in thinking that laws permitting insane criminals to go unpunished must be defective, and that a dangerous and pernicious precedent has been established by this case. True, a man's grief over his sister's disgrace may cause temporary insanity, but that hardly excuses the crime ; and may not one whose emotions have once caused insanity be regarded as predisposed to such attacks ? and are

the lives of those who are thrown in contact with such persons safe ? We think not ; and the sooner more perfect laws are framed for these cases, the less risk and frequency will there be of murders committed by those who afterwards are declared insane.

There is no more important question to engage the attention of legislators than this ; the plea of temporary insanity is so often made the means of cheating justice, that it is high time a stop was put to it.

It would be inhuman, and against the dictates of all law, human and divine, to advocate the execution of an insane man ; but some provision should be made that would render him harmless to his fellow-citizens.

OUR NEW SANITARY LAWS.

We are about to have offered to councils an ordinance designed to improve the sanitary condition of our dwellings. The ordinance provides that the drainage of all buildings hereafter erected, as well as the plumbing and drainage, shall be executed in accordance with plans approved by the Chief Engineer and Surveyor or a duly authorized assistant. Each building must be connected with its own sewer. House drains must be of iron, and in those manufactories where chemicals would corrode iron, glazed pipes may be used. Soil and waste pipes must be of iron. The Chief Engineer and Surveyor is directed to prepare agreements and specifications for the construction of drains leading to the street sewers, and no drains shall be paved over unless the work has been inspected and approved by the Survey Department. The city shall be divided into five districts, and an inspector, who shall be an experienced plumber, shall be appointed for each district. Every master or journeyman plumber, carrying on his trade in the city shall register his name at the Survey Department. A penalty of not less than \$20 nor more than \$50 is to be imposed for each violation of the ordinance.

While such laws are great necessities, and in the abstract are most beneficial to mankind, yet

there is one objection which we note. *The inspector shall be an experienced plumber.*

This looks very much as though there might be a *trade* element involved in this hygienic reform. Would it not be better to have a competent physician, who had made a special study of sanitary matters, to look after this drainage? He would have no incentive to approve defective or to condemn efficient work. We commend this amendment to our law-makers: if they really desire to do their fellow-citizens a benefit, they will give heed to it; if not, they will give it no attention; and though we hope not, yet we fear that the latter will be the reception our suggestion will receive.

NOTES AND COMMENTS.

Lancing the Gums of Children.

After stating that it is proper to lance the gums when they are swollen and either red from inflammation or white from pressure of a tooth coming, Dr. Chase, in the *Mo. Dental Journal*, goes on to say:

"The operator should *know* whether a tooth is pressing on the gum, and trying to make its way out. In this case, *cut down to the new tooth*, until it is felt under the lancet. For incisors and cuspids, a straight line cut. For molars, a cross-cut.

"How *not* to do it: Not with a child sitting up, in your lap, or any one's lap.

"*How to do it*: 'Let the operator and 'nurse' sit close together, facing each other. The child is laid down, face upwards; the head in the operator's lap, the feet in the 'nurse's' lap. The nurse holds the limbs of the child quietly, so that it may not interfere.

"With the left hand the operator takes the jaw between his fingers, and slowly and firmly does the cutting.

"There is no false cut. The child is still."

On Abstraction of Blood from the Right Heart, as a Means of Relieving Intense Pulmonary Congestion.

Dr. Benj. F. Westbrook, in a paper in the *Medical Record*, records a case of the above in a man of about fifty years of age, with almost instant relief, but unfortunately, as it was used as a *dernier resort*, the relief proved only temporary.

In using the puncture, he gives explicit description of the anatomical situation of the heart and

valves, and the place where the tapping should take place.

The *right auricle* is the most available point for tapping, inasmuch as its position is less variable than that of the ventricle, and its accessible portion more globular, with a greater antero-posterior diameter to allow of free penetration of an instrument without danger of its passing through into the posterior wall. As an additional advantage, he also gives the following propositions:

First. The right auricle projects to the right about equally in the third and fourth intercostal spaces.

Second. Its perpendicular depth varies greatly according to its distention and the condition of the left heart and lungs.

Third. The projection to the right is greatest, and the perpendicular depth least when the right heart is distended, as in a death from coma and asphyxia.

Fourth. The internal mammary vein, which lies upon the sternal side of the artery, is very constant in its course, and situated, on an average, about one centimetre external to the right border of the sternum.

Fifth. The anterior border of the right lung almost always extends inward beyond the border of the sternum, reaching, or even passing the median line in many subjects.

He gives preference to tapping in the third interspace for two reasons: First, because it is much wider than the fourth, and the needle passes with less difficulty; Second, because the line of the fourth would direct the needle more toward the auriculo-ventricular opening, where it might come in contact with the tricuspid valve.

Chloroform in Children.

A writer in the *Cincinnati Lancet and Clinic* says that in his experience chloroform in children is not as safe as is generally supposed, and he relates two cases of death following the administration of the anæsthetic. His conclusions are that chloroform causes death by enfeebling the heart, while ether paralyzes the lungs. Death from chloroform commonly occurs during the first part of the administration, or rather from the first inspirations.

Locomotor Ataxia Complicated by Acute Cardiac Disease.

Dr. L. Weber, of New York, reports such a case (in the *Medical Record*) and refers to its rarity. There is no doubt that the condition of the heart is very often overlooked, on account of the

seriousness of the original factor, the "ataxia." "In the cases that have come under my care, there has *always* been heart complication."

Particular attention should be paid to restricting sexual intercourse. "In the case of a woman that came under my care, excessive sexual intercourse was the undoubted cause of hastening death."

Ossified Muscle.

Dr. Carson reported such a case to the Medico-Chirurgical Society. A child had what seemed to be complete ossification of the sterno-cleido-mastoid; it was not quite as hard as bone, but much harder than cartilage. There was free motion of the head, including rotation. It will be found in the *St. Louis Courier of Medicine* for Dec., 1882.

Ergot in Epithelial Cancer.

Dr. Wm. A. Collins had a case of cancerous affection of the face in which the use of a knife or cautery was precluded. It occurred to him to try the effect of ergot to diminish the vascularity and capillary circulation, and thus limit the excessive cell-growth which forms the characteristic feature of these conditions.

Fresh ergot, freshly ground to an *impalpable* powder was applied dry, by means of a soft hair pencil, to the whole surface of the ulcer thrice daily. The ulcer was washed off carefully once daily. After each application the ulcer was covered with a light muslin rag, wet with the following lotion:

R. Acid. carbolic,	3 i.
Acid. sulphurosi,	3 j.
Glycerinæ,	3 iv.
Aquæ,	3 ijss.
M. S.—Lotion.	

Tonics were administered. In twelve weeks the whole ulcer had healed, and has remained so now for four years. In a case of mammary cancer, where an ulcer five inches in diameter and one inch deep occupied the site of the destroyed gland, and the axillary glands were involved, an equally complete though less rapid cure was obtained. The author, who reports these cases in the *Cinn. Lan. and Clinic.*, relates several other successful cases. These results entitle this treatment to further trial.

Fecaloid Vomiting from Arrest of Menses.

M. More Y. Bragit reports an interesting case in the *Annales de Obstetrica*, p. 114, 1882. A married woman 38 years of age, without any preliminary chill or headache, was attacked with constant vomiting, accompanied with pains in the abdomen not fixed at any one point. This vomiting con-

tinued three days; there was no passage from the bowels, and the matters ejected from the stomach became fecaloid.

No trace of hernia could be found, and the only fact to favor the supposition of internal strangulation was the nature of the matters vomited.

Opium and bicarbonate of soda in potion were rejected almost as soon as swallowed, as also pills containing the same ingredients. Sulphate of soda was then given, and enemata containing oil of sweet almonds administered, while frictions with an ointment containing belladonna were made over the abdomen. The following day the vomiting persisted, ice was given, and pills containing colocynth and aloes. The following day she had but one discharge from the stomach, of a fecaloid nature, and another during the night. The patient called the attention of the physician to the fact that the menstrual flow was just commencing. It should have occurred on the week previous to the commencement of her malady, but had been suppressed, owing to the effect on the patient of family troubles.

From that time measures were taken to favor the menstrual flow; gradually the vomiting ceased, and fifteen days later the patient was completely restored to health.

CORRESPONDENCE.

Medical Laws in Mercer County.

EDS. MED. AND SURG. REPORTER:—

Our medical laws have just received a partial test in this county, with a result which may interest your readers—especially those resident in this State. The Mercer county Medical Society appointed a committee on registration in July, 1881, of which the writer was chairman. It was at once discovered that our prothonotary was no proper judge of the article called a diploma—as an irregular had registered within a few days after the registration law became known a certificate of membership in a medical society, averring with great earnestness that it was equal to, and as good as, any man's diploma in the county. He had been practicing in the State since June, 1871, and when he found he would be prosecuted, he registered on the ten years' limitation. Some time afterwards another variety of irregular registered another certificate, signed by one man only, but declaring that the recipient had pursued regular courses of study in an institution to which he gave a pompous name, but which was unknown to us and to the secretary of the State in which it was located. Another man kept a sanitarium in which he received patients for treatment with electricity. His card was "Dr. B., medical electrician." This man had not practiced continuously since 1871, and could not register. A few years ago he was a coal miner. Informations were made

against these last two, and on the fourth inst. our grand jury found true bills. Both men had been rather defiant, but now became thoroughly alive to their danger, and sought the privilege of settling. The society only desired to test the law, and was in no degree desirous of inflicting fines or penalties. So it was agreed that they should plead guilty (we had ample proof had they declined to do so), and be let off as easily as possible—that each defendant should pay the costs of his suit, and stand convicted. The judge told them that he would sentence them on their own pleading, in case any future complaint of their having violated the law should be heard. Judge McDermott of our court is one of those men who believe the laws are made to be enforced, but the prosecution did not wish the penalties inflicted in these cases, desiring only to accomplish what was necessary for the public good. E. GRISWOLD, M. D.

Sharon, Pa.

Treatment of Scarlet Fever.

EDS. MED. AND SURG. REPORTER:—

The theory, that in all zymotic diseases, there is a peculiar germ causing its own peculiar disease, I believe to be true. And in order to destroy the germ causing the disease, antiseptics must be used. The Listerian method is the one now in use in surgical and gynecological treatment. If under the spray the pus-producing germ is destroyed externally—can we not destroy this germ in the system, and thereby reduce the great fatality which attends scarlatina especially.

Upon this theory I have been treating an epidemic of scarlet fever, which has been in our neighborhood for several months. A large majority of the cases have been very severe, from beginning to the end. In my own practice I have treated thirty cases and have lost only one, and that was due, in my opinion, to the patient not being made to take the medicine.

When called to a patient—and it was generally when the rash was fully out—I at once ordered chlorate of potash and *carbolic acid* internally, with inunction of the whole surface of the body. This treatment was pushed throughout the whole course of the disease, with the most gratifying results.

I have looked in vain for a confirmation of my views in Flint, Smith, West, and others. Prof. Smith does recommend carbolic acid as a gargle—but not as an internal remedy. The only writer recommending this treatment, and entirely in accord with my views, is Dr. McDonald, in *British Medical Journal*. He treated six cases, all of which recovered. I trust that this treatment will be tried by the profession, believing that more successful results will be secured from it, than any known remedy. JOHN W. AYLER, M. D.

Duffield, W. Va.

Morphine Poisoning Treated With Strychnia.

EDS. MED. AND SURG. REPORTER:—

I was called to see a young lady who was said to be dying from an over-dose of morphine. On my arrival I learned she had taken one drachm of morphia. I found her profoundly comatose, respirations three per minute; face almost black, pupils

would not respond to light. I gave her immediately $\frac{1}{2}$ gr. of sul. strychnia, hypodermically, and waited fifteen minutes for the result. I saw some improvement in respiration, and gave her another $\frac{1}{2}$ gr. dose, and waited a quarter of an hour more, when I was astonished at its antidotal power over the poison. She could be aroused and talk when spoken to; I waited a half hour from the second dose and gave her the remaining $\frac{1}{2}$ gr., and after a few minutes I saw I had her under the influence of strychnia; the facial muscles warned me to wait awhile before I gave her any more. So by waiting awhile she recovered sufficiently to swallow coffee, I had her take large quantities of coffee every hour, and gave her, per ore, $\frac{1}{15}$ gr. of strychnia every four hours till she fully recovered. She recovered in forty-eight hours sufficiently to sit up, and grew better rapidly.

I have treated one more case since then, with the same success.

C. A. MASON, M. D.

Blanchard Springs, Union County, Ark.

Treatment of Diphtheria.

EDS. MED. AND SURG. REPORTER:—

In reply to the inquiry of W. J. H., M. D., Ohio, I have placed my reliance in the treatment of diphtheria and analogous diseases of the mouth, fauces and throat, upon a combination of equal parts of chlorate and iodide of potash. My formula is:

R.	Iodide of potash,	
	Pulv. chlorate of potash,	āā ʒj.
	Aqua destil.,	ʒiv.

M. Shake well; single dose, a teaspoonful every half hour to an infant under five years; a dessert spoonful to a child under ten, and a tablespoonful to one over ten years every half hour.

Under this treatment, premised by a grain or two each of calomel and rhubarb, I have always had, in a majority of cases, the gratification of seeing the white patches disappear from the throat in the space of a day or two, and at the end of a week the infant or child convalescent. Diphtheria is a disease sudden in its attack and rapid in its progress, and the slow process of giving medicine every three or four hours is too remote to be relied upon; for the object is to saturate, as it were, as early as possible, the system with those medicines that experience has taught to possess an apparent, if not real, specific effect in the diseases of the throat; and this object is most readily attained by giving these two preparations of potash at short intervals. The mixture is clear and almost tasteless, and if children are not told that it is medicine they will take it as readily as they take water. This treatment can be rationally explained by the fact that diphtheria is a disease not only of the mucous membrane of the fauces, but of the glands of the throat also; and these two preparations of potash, to a greater efficacy than any two other known drugs, act specifically on the diseases of the mucous membrane of the mouth and the glands about the throat. Thirty years' experience has taught me to rely with as much confidence on the use of this combination of iodide and chlorate of potash in the treatment of diphtheria, as I do upon the sulphate of quinine in the treatment of ordinary in-

termittent fever; and so confident am I of relieving my little patients with diphtheria with the potash treatment, I feel no more concern about its treatment than I do about the treatment of a case of ordinary chills with quinine.

Prosser James, M. D., in his book on sore throat, says: "Chlorate of potash may be tried by those who have faith in it, and recently some fresh testimony has been adduced in its favor, but other drugs are more to be relied on. Dr. Wilmoughby Wade combines it with iodide of potassium, and, where this last drug was vigorously pushed in five or ten grain doses every two or three hours; he reported unusual success, with no subsequent paralysis." And my own experience is precisely in accordance with that of Dr. Wade. In very severe cases I sometimes use as an adjuvant the following:

R. Ammonie muriat.,	grs. xxx.
Tinct. ferri muriat.,	ʒj.
Syrup simp.,	
Aqua destil.,	aa ʒ ij.

M. Shake well. Sig.—A teaspoonful every two hours to a child, and as a gargle and wash for the throat, mouth and nares I use the following:

R. Sod. hyposulphite,	ʒ ss.
Acid. carbol.,	ʒ ij.
Aqua destil.,	ʒ iv.
Glycerine,	ʒ ij.

M. Shake well and use freely three or four times a day when necessary. For infants and children I prescribe a milk diet exclusively, and this I allow to be given at pleasure. I have the throat bound with flannel, and keep the children in a warm room with a temperature of about 65 degrees, and free from cold draughts of air until they are well. For thirty years, under this treatment of diphtheria, my efforts have been rewarded by the most gratifying success.

J. B. JOHNSON, M. D.

Washington, D. C.

NEWS AND MISCELLANY.

Another Centenarian.

The *London Medical Times and Gazette* says that the death is announced of Thomas Bramley, a resident and native of Ilkeston, in his one hundred and fifth year, he having been born on Christmas eve, 1777. Until very recently, Bramley, though afflicted with lameness and deafness, was in full possession of his mental faculties. He leaves a large number of descendants, and a son seventy years old.

The Weather in Italy.

The autumn and winter in Central Italy thus far have been rainy and sunless to an unprecedented degree. Since October there have been no two days of consecutive sunshining, and few days without more or less rain, while several heavy snowfalls have occurred. The season has been as cheerless a one to people looking for sunshine and a mild winter as they would have found anywhere on the Atlantic coasts. Florence is very full of

strangers, who are experiencing discomforts that are not to be found in the visions of sunny Italy in which people at home indulge.

Still Another Centenarian.

The death is announced, at the Protestant Retreat Drumcondra, near Dublin, of Mrs. Mary Murray, at the age of 110 years. She was a native of the county of Derry, and for many years carried books about for sale, throughout the entire province of Ulster, and many portions of Leinster. She was a very tall, strong woman, and was admirably fitted for the wandering life she led previous to her admission to the Retreat. Mrs. Murray is said to have been fond of a glass of punch, and smoked a very black dhudeen up to a very few years ago.

The Marine Hospital Service.

The Maritime Exchange of this city has memorialized Congress against the transfer of the Marine Hospital Service from the Treasury to the Navy Department.

Our Mortality.

The deaths in this city for the week ending January 20 numbered 407, which was 17 more than the previous week, and 43 less than for the same period last year. The main causes of death were: Apoplexy, 11; consumption of the lungs, 66; convulsions, 13; croup, 13; debility, 15; diphtheria, 28; disease of the heart, 18; typhoid fever, 12; inflammation of the lungs, 42; old age, 17.

Our Almshouse Hospital.

At the meeting of the Board of Guardians of the Poor, January 22, the Committee on Outwards reported that the cost of proper ventilation of the hospital would be about \$9,000. They believe there are but fifteen paupers who could make a living if discharged. A resolution was adopted approving of the removal of the pauper inmates of the outward department to an almshouse proper, to be erected adjoining the House of Correction, and that the present buildings be connected with a municipal hospital. This is a mistake. The whole thing should be removed, and the buildings razed to the ground; they are saturated with disease, and are perfect pest-houses—let us have done with them.

Do Not Keep Anatomical Specimens in Your Offices.

The *Medical Press and Circular* says that the Hon. A. B., a valetudinarian of 65, went to consult a leader of science. The physician was out, but his valet announced that he would be in soon, and, on learning the position of the client, introduced him into his master's private sanctum, so that he might have the benefit of consulting him out of his turn. To pass away the time, the patient examined the room, and discovering in one corner an excellently mounted and complete skeleton, imagination immediately suggested that this was probably an old patient of the doctor's. He flew at once to the hall-door and rapidly vanished, to the astonishment of the servant and the subsequent annoyance of the physician.

Personals.

—A homeopathic physician of this city recently had to defend himself in a suit brought by a young woman whom he had sent to the smallpox hospital when she only had measles. He was acquitted, however; his defense being that he believed it to be smallpox, and that the early stages of the diseases are alike. (1)

—Samuel Gast, of Iowa, and his nephew, David Gast, of Ohio, traveling cancer doctors, and James E. Haines, a student, of Rising Sun, Md., were arrested January 23—the two first mentioned at Bellefonte, this state, and the latter at his home—on a Coroner's warrant, charging them with homicide, in having caused the death of Mrs. James Armstrong, aged seventy-three years, of Chester county, whom they treated for cancer. W. J. Perkins, of Chester, who harbored the trio of cancer doctors, was also arrested on the charge of being an accessory to the homicide. The entire party have been lodged in Media jail to await trial.

—The "Mountain Evangelist" Barnes cures thousands by the "laying on of hands" and prayer. In one of his recent harangues, he said: "I'm not a homeopath, or an allopath, or a hydro-path. I am a Jesupath, and I wouldn't give my doctor for a hundred others." When will such exhibitions of superstition and credulity cease?

—Robert J. P. McClatchey, a leading homeopathic physician of this city, died last week. He had for years been President of the Homeopathic State Society and the county society of this city. He was a man of literary attainments, having written largely for the homeopathic journals of this country, and was for ten years editor of the *Hahnemannian Monthly*.

—The Rev. Dr. Hicks, of the Tabernacle church, who was the spiritual adviser of Charles Guiteau, has executed a legal instrument, transferring to Surgeon-General Crane, U. S. A., all his right and title to Guiteau's body. The paper recites the clause of the will by which Guiteau bequeathed his body to Dr. Hicks, and it bears evidence of acknowledgment before a justice of the peace. In reply to inquiries, Surgeon-General Crane said he was unable at present to give any information with regard to the final disposition of the assassin's remains.

Items.

—Beware how you "chaff" a chemist, for his retort is always ready.

—One hundred and ninety-six bodies have been cremated in Milan in the last five years.

—Dr. Jacobi recommends closing the mouth and blowing into the nose in the earache of infants and children.

—The fluid extract of tomato is recommended in nursing sore mouth and cancrum oris.

—At an auction sale of old government medical supplies, at St. Louis, among other things one man bought 17,308 pills for thirty cents. A local paper says, "The books and instruments sold had been used before, but the pills were entirely new."

—Body-snatching is reported from Montreal.

—Advice from a sanitary engineer in building a house is as valuable as that of the architect.

—The third lecture of the course on "Sanitary Engineering" was delivered at the Franklin Institute January 22, by C. Henry Roney, C. E.

—Dr. Walter Carpenter has been elected president of the Board of Directors of the Mary Fletcher Hospital, Burlington, Vt.

—The Board of Health of Philadelphia reported last week 93 cases of diphtheria, of which 22 were fatal.

—A Seiator, Ill., doctor sent a bottle to a patient labeled, "Calmel-pizen." The County Medical Society has cited him to appear and show cause why he should not be expelled.

—A despatch from Dallas, Texas, states that on January 16, a family of nine persons were poisoned by eating pork supposed to be trichinous. Three of them died.

—On January 17th, Mr. P. Schumacher, one of the oldest citizens of Fayetteville, Ohio, suddenly dropped dead in the midst of a hearty fit of laughter.

—Major Setemup don't believe in the water of our city. He is reported to have described it as follows to a recent visitor: "Why, sir, you wouldn't believe it, bein' a stranger, but that year the water got so infernal foul that a quack doctor down in my neighborhood bottled it and sold it for a new mixture of cod-liver oil and lime. My wife made up her mind she'd bile the stuff afore using it for washing purposes, and the smell of it was so spanking strong that the first thing I knowed some of the neighbors had me indicted for running a soap factory inside the city limits. I got the Mayor and Health Officer to come up and examine the premises, and if you'll believe me, they went around and offered a free right of way to any man who'd agree to start a bone-biling shop, just to dilute the flavor of the atmosphere. I'm agin Schnyylkill water under all circumstances;" and the major blew the foam off his glass of export beer, and eyed it with entire approval.

 QUERIES AND REPLIES.

F. K. M., *Mt. Morris, Pa.* We would refer you to Bartholow's Practice of Medicine.

 MARRIAGES.

RAYNES—DAVIS.—In Lebanon, January 17, at the residence of the bride's father, by Rev. M. V. B. Knox, D. D., assisted by Rev. J. M. Dutton, John B. Raynes, M. D., of Bradford, N. H., formerly of Lebanon, and Emma A. Davis, daughter of James A. Davis, M. D.

SMOCK—BRADFIELD.—On Saturday, January 6, 1883, at First Church Disciples of Christ, by Rev. O. A. Bartholomew, Ledru P. Smock, A. M., M. D., and Jessie V., daughter of John B. Bradfield, both of West Philadelphia.

WHITE—HOWARD.—On Wednesday evening, January 10, at Old Pine Street Presbyterian church, by Rev. H. O. Gibbons, Dr. C. Garrison White and Lizzie K. Howard, both of this city.

 DEATH.

CHALFANT.—In Kansas City, Mo., January 12, Dr. David Y. Chalfant, aged 52 years.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

*A chalybeate that has all the virtues and none of the defects of all the
present official preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for
which all the above claims have been verified, both in the laboratory and by the clinical experience of many of
the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and
being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of
the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting
from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's
Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds
containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be
claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added
to a solution of a ferric salt. Free Nitrogen, however, added to Solution Ferrous Malate will turn it black in-
stantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts.,

CENTRAL AMERICAN MEDICAL CURIOSITIES COLLECTED FOR THE MEDICAL AND SURGICAL REPORTER.

BY FERD. C. VALENTINE, M. D.,
Of New York.

(See pp. 397 and 617.)

Toads have a more extended application. The live animal is slit open along its ventral surface and is lightly passed over erysipelatous parts, which treatment is said to cause the disease to abort immediately "by absorbing the hot blood of the patient, and giving him the toad's cold juice in exchange." My informant blissfully asserted that the same treatment would cure cancer—he had never heard of condurango.

Powdered willow-bark, two drachms a day, is said to cure quartan intermittents, and an anti-gangrenous poultice is made of equal parts of the powder and ground rue (*Ruta, L.*) made into a pasty consistency with aguardiente, vinegar and liquidamber, also in equal parts.

Elder flowers (*Sambucus*) in infusion are presented in catarrhal, eruptive and rheumatic affections. The flowers are mixed with bran in equal parts, and tied upon erysipelatous parts. The flower is soaked in white wine, "which then will give the drinker a sweet voice," and the leaves applied to the breasts are said to arrest the secretion of milk.

Cow's tallow melted and mixed with warm water is drunk to relieve old pyrosis. Lavender, cinnamon and copalchi, in powder, are added, and the resultant mixture is applied externally to

painful joints. In dysentery, a drink is given *ad libitum* composed of mutton tallow, ten ounces, and cow's milk, eight ounces, which are boiled together over a slow fire, and continuously stirred from left to right. Subsequently, a teaspoonful each of starch and sugar are added, and the whole boiled again.

Rosemary is employed in infantile convulsions and epilepsy, and externally as a cosmetic and to intensify visual power.

Infusion of red roses, and oil of red roses, the latter made by adding two ounces of the leaves, which have been dried in the shade, to a pint and a half of fresh salad oil, which, in a well-stoppered bottle, is boiled in water for two hours, are used in slight burns and superficial inflammations.

Decoction of white rose is an excellent purge for children *when given with manna.* (!)

Rue is the cardinal remedy for all nervous affections, especially hysteria and epilepsy. It strengthens the sight, "dissolves pannis" (the fresh sap is squirted upon the opened eye every morning) and is a vermicide. Some mothers give 20 grains of the powder every morning to their daughters, because, "with prayers and fasting it temporarily quiets the sexual desires, facilitates menstruation, and will make future parturition easy."

A favorite hysteric potion is made of three tablespoonfuls of fresh ruta-juice and six of infusion of orange leaves, of which a tablespoonful is given every hour.

A paste for common intermittent is composed of half an ounce each of ground rue and mustard, to which a sufficiency of water is added, and the wrists and soles are besmeared with the mass at

the inception of the chill. I have frequently witnessed this application, and can assure my readers in all gravity and candor that it never had any effect further than to please the patients' grandmothers, which, however, is frequently not an unimportant element to professional success.

Modern medicine and elegant pharmacy are doing their iconoclastic work with the granny-doctors of Central America, and although they progress somewhat slowly, it is safe to say that another generation will relegate much of the "nasty" of to-day to the *panteón*, and R. I. P. will be written over it.

Having thus relieved myself, I shall return to the rue, the leaves of which and those of anise, an ounce and a half each, are added to a quart of strong aguardiente. They are placed in a well-corked bottle and exposed to the sun for eight days. Two tablespoonfuls are given in half a glass of sweetened water before the chills come on, from which it will be correctly inferred that this tincture is a favorite prescription for intermittents. As in a majority of other instances, the "stomach of the patient must be thoroughly cleaned out before using this remedy"—and thoroughly cleaned out it is, if ipecac in almost unlimited quantities can do it.

I believe that there is in this world no more frugal people than the Central Americans, and at the same time no people more fond of vomiting. I know of a case in San José de Guatemala, a carpenter who fell from a house and sustained a compound comminuted fracture of the femur. The surgeon of the local garrison was called, and previous to examining the patient gave him 40 grains of ipecac. The North American stomach repudiated the dose and the breakfast. The man is alive and well to-day, with very little shortening. When I asked the surgeon why he had given the ipecac, he told me, "to clean out the stomach and relax the muscles."

For the good repute of my colleagues, such as Pacheco, Alvarez, Cárdenas, Luna, Monteros, Fenner, Fernandez-Padilla, P. Molina-Flores, *et id omne genus*, I must explain that my friend above cited is by no means a type of the Central American physician, many of whom would attain a foremost rank in the profession, if they limited themselves to it.

Common salt, one to two ounces, in half a glass of warm water, is given as a purge. Intestinal worms are treated by giving patients strongly-salted food. Vinegar and salt is applied to bruises and inflamed swellings, and recently the use of a drachm of salt in half an ounce of brandy has

been recommended to be taken every morning in intermittents and phthisis. Salt fried in lard is applied to the swollen face which frequently accompanies odontalgia. Fomentations of hot salt-water are applied to painful joints. An anti-phthical pill is made of common salt a drachm, toasted and ground acorns a drachm and a half each, conserve of roses a sufficiency. The mass is divided into forty pills. One is taken every hour for a month.

Nitrate of potassium, "refreshes and increases the urine, impedes putrefaction, and calms the ardor of the blood," meaning "restrains animal passions," for which purpose it is rarely taken. It is recommended in all inflammatory affections, variola, scarlatina, rheumatism, and in dropsy (3j. daily in barley water or beer). Stout women when pregnant, take cream tartar 3j. with the nitrate 3j. div. in chart. No. viii, one every three hours, to relieve toothaches and so forth, incidental to their condition.

Dragon's blood, with rose-water or plantain sap, is given in metrorrhagia and diarrhœa, two or three tablespoonfuls a day, or 12 to 24 grains of the powdered dragon's blood. It is also used in ulcerative stomatitis, as a mouth wash to cleanse and "fasten the teeth."

Tobacco is given internally in chronic catarrhs and dropsy. A decoction is injected to kill ascarides, and it is prescribed in asthma, apoplexy, paralysis and strangulated hernia. Externally it is used for tinea, itch, and is applied to ulcers which have become infested with maggots.

Tincture of tobacco is made by infusing two drachms of the leaves in four ounces of boiling water. They are left there for two days, then strained, and three tablespoonfuls of aguardiente are added to the liquid, the dose of which is 20 to 40 drops.

A cerate for herpes of all kinds is made of three ounces each of the juice of green tobacco, yellow wax, and turpentine, with a small quantity of oil. These are melted together and applied to the herpetic spots.

Headaches, neuralgias, and other painful affections, are treated topically with a tobacco leaf and oil. I would here write a eulogy of Honduranian tobacco, especially that of the district of Santa Rosa, if I did not fear the unappreciative editorial blue-pencil, which does not smoke. The sweetened infusion of fresh tamarinds is given in fevers, especially those of the bilious type. The decoction of the flowers is an excellent diaphoretic. The flesh of the fruit is spread upon soft leaves or rags, and applied to abscesses as a maturative.

Tamarinds are preserved by removing the seeds and adding two parts of sugar, and grinding the mass together. Stramonium "even in small doses causes madness and other disorders." It is an excitant and a narcotic, and is used to cure nervous rheumatism, convulsions, to quiet maniacs and to give them sleep." The dried leaves are smoked in asthmatic attacks; to facilitate their action the patient is advised to drink strong coffee while smoking. All local pains are treated by poultices of the mashed stramonium leaves. "Turtle-flesh should be given wives who do not love their husbands, as their genital appetite will be so stimulated that he will be welcome at all times. It also purifies the blood, and in erysipelas turtle-soup should be taken extensively, and the affected parts anointed with the turtle's blood."

This is an instance of the very common belief in aphrodisiacs, a subject which in all times has had great attractions for the popular mind, and on equally slim foundations.

Turpentine is used in chronic intestinal and bronchial catarrhs and in blennorrhagia.

The leaves of the tuna (sold here under the name of the "Mexican prickly pear") are applied upon any inflamed part, when the inflammation is not dependent upon traumatism. The gum of the plant is considered expectorant, and the red petals of the flower, ground and mixed with sugar, are given in old gonorrhœas.

The vanilla of Central America offers a chance to some physician whose passion for his profession is not so great that it precludes other occupation. It is larger and finer than the Mexican, but no one in Central America understands its preparation for the market. The specimens brought here are not sufficiently dry. The non-professional prescribers of Central America say it is nervine and analeptic, but too aphrodisiac to take carelessly. Perhaps that explains its extensive use. The tincture (1 to 10 of aguardiente) is given in 40 to 60-drop doses in wine.

"Deer meat prolongs life." The tallow melted in manzanilla water is given as a 'pectoral' at the conclusion of pneumonia, and it is also applied to abscesses. Filings of deer horns are given in wine to people infested with lice.

Portulacca is recommended as a diet in constipation, and the juice is said, by some physicians, to be entirely reliable in tape-worm. The dose is three tablespoonfuls every fifteen minutes, fasting. This is continued until the worm is expelled.

Peppermint is used as in other parts, but it is urged that at least every three years the plant

must be removed from the site of its growth, otherwise the leaves lose their medicinal virtues.

The horse-aloe is quite common in all of the hot coast-regions of Central America. Incisions are made into the leaves during the ascending quarter of the moon; from these incisions the thick sap flows which soon grows hard and is scraped off. It is used as a cathartic in dropsies, and is given to women with amenorrhœa. A watery saturated solution is employed as a wash for chronic ulcers, maggots, lice and bed-bugs. It is injected for intestinal worms and applied to gangrenes.

The mucilaginous sap of the leaves is used as a dressing in recent burns and erysipelas, and is efficaciously employed in acute urethritis, 9 tablespoonfuls of the fresh juice with the same quantity of milk drank fasting. A popular iron and aloes pill is made of iron filings (q. v.), 100 grains to 40 of powdered aloes, with a sufficiency of thick mucilage. This mass is divided into 50 pills, and four to six of these are given daily to anæmic persons and to women said to suffer from metritis. I intentionally throw doubt upon the diagnosis, as physical exploration of the female genitalia is rarely allowed in the greater part of Central America, for a very sad reason, one which reflects horribly upon the profession, and I am glad to say that the implied charge is as unfounded as it is villainously unjust.

Tincture of aloes is composed of an ounce of the gum dissolved in a quart of aguardiente. Ten to twelve drops are taken in wine or water in the morning to "open the appetite and give strength to weak stomachs." (!) "This tincture must not be given to pregnant women, nor to persons who suffer from hemorrhoids, as it will make them worse."

A curious vermifuge ointment is made of cow's bile and powdered aloes, two drachms each to an ounce of lard. These are well rubbed together and anointed upon the umbilicus to kill intestinal worms and to assuage the colic-like pains produced by them.

Another infallible remedy for *nube*, i. e. all opacities of the cornea, from slight leucoma to the most dense pannus, is made of six grains of powdered aloes, thoroughly triturated with seventy-two grains of white sugar. The powder is blown through a quill upon the eye while the lids are opened. It is not necessary to comment upon this treatment.

Sarsaparilla, which abounds on the North (Atlantic) coast of Honduras and Guatemala, both of which are called in the market "Honduras Sar-

saparilla," and are known for their superiority, have as wide a medicinal application in Central America as the domain of pathology reaches. It is used in infusion and powdered and in all conceivable doses, by the lower classes, while those better situated prefer the foreign preparations, such as the fluid extract, tincture, and syrup.

Sassafras is considered diuretic, diaphoretic, and sedative. It is prescribed in syphilis, sterility, and rheumatism, in doses of a drachm daily in powder.

The Central American leeches are small, and do not extract more than three-quarters of a drachm of blood. They are not much used.

A few words now upon the general indications for treatment.

Enemas of cold water are administered for cephalalgia; of purgatives for their effect; of starch with laudanum to calm pain, and as an hypnotic; of decoction of quinia, or with sulphate of quinine in pernicious fevers; of malva with nitrate of potassium, for ardor urinæ and retention of this excretion; of decoction of rue or artemisia in nervous or flatulent colic, and for rectal alimentation.

Purgatives.—Drastics are forbidden in pregnancy, dysentery, hemorrhoids, or debility; but their use is urged in apoplexy, dropsy, and amenorrhœa. Laxatives are proper in dysentery and bilious diseases. Persons having taken a purge should limit their diet, "lest they produce dysentery, indigestion, and dropsy."

Sinapisms should not be prepared with vinegar nor aguardiente, as thus their virtue is destroyed. When a strong sinapism is required, only water is added to the ground mustard, and flour is added when a mild effect suffices. They are used on non-inflammatory painful parts, and they are applied to the nucha and the soles in dizziness and headache. If placed over enlarged spleen they reduce its size, and cause fevers to abort; upon the stomach, they materially help obstinate vomiting and diarrhœa.

Dry cups are applied over the stomach to relieve vomiting, and to the breasts and back to restrain uterine hemorrhage.

Emetics should head the list for the wonderful—I nearly said outrageous—frequency with which they are employed. "They are the most natural remedy: they promote perspiration and cause a healthy 'shaking up.' They are suitable in bitter taste and pestilential breath (literal translation), also to calm nervous diseases, rheumatism (of course) and dementia"—in brief, to all the ills that flesh is heir to, and which can be conjured

up by the imagination of people who have little to do. Yet it must be remembered that emetics "must not be given in gastritis, or when the tongue is red and dry, and when the patient is vomiting or very constipated. Nor are they suitable in pregnancy, during menstruation, nor when the patient has hernia, or apoplectic tendency."

In conclusion, let me repeat that this brief review of the non-professional *materia medica* Centro-Americana, though, perhaps, the foundation for a future scientific one, is by no means a fair picture by which to judge the brilliant practitioners of the larger cities. I present the list merely as a collection of curiosities, from which a great many really valuable ideas can be culled, and lay down my stylographic pen, which has inked me so far as my elbow, as I rest to conjure up a dream of Central America—of the delights of practice and life there. However, I shall not inflict more upon the editor, who has been already too indulgent with my senile garrulity; I will only ask him to permit me to add the proverb:

"De médico, poeta y loco
Todos tenemos un poco,"

which may be freely rendered—if the readers are not too exacting:

"In all men's and women's humanity
Are some medicine, rhyme, and insanity."

Which predominates? which should take precedence? And deponent further sayeth not.

SICK HEADACHE.

BY DAN'L B. D. BEAVER, M. D.,
Of Reading, Pa.

There appeared in the *MEDICAL AND SURGICAL REPORTER*, on the 29th of last July, an article from the pen of Dr. G. C. Savage, of Jackson, Tenn., upon "*Sick Headache: Its Causes Hypermetropia and Astigmatism, either alone or combined, and its cure, properly-fitting glasses,*" which by reason of having found its way into the lay press* demands more professional attention. So long as it remained in the medical journals, the author alone was responsible for its statements; but as soon as non-professional papers quoted and copied it for the public eye, the profession became sponsor, and will receive honor or dishonor according to its truthfulness. If Dr. Savage has actually "discovered the real cause and treatment of sick-headache, that opprobrium of medical art from the beginning down to the present time," as he claims, he has conferred a boon upon humanity, and indeed re-

* *Christian Advocate*, New York, Nov. 30, 1882.

moved the "opprobrium" of our art; but if his claim is not well founded, he has added one more to the ill-advised and indiscriminately-vaunted cures which have made this disease a reproach to the profession. Let us see on which side he is. What has he discovered? Nothing more than that his own (and his mother's) headache was owing to hypermetropia and astigmatism. He has not brought to light a single new scientific fact.

If he had examined the literature of this subject, he could have learned long ago that certain cases of sick-headache are dependent upon weakness of the eyes, which in its turn is frequently chargeable to the presence of optical defects.

Half a century ago Gorget and Calmeil* observed that naturalists who pass many hours in the examination of small objects, which sometimes require to be magnified with the microscope, under strong light, are subject to this painful disease of the head (cephalalgie). These gentlemen did not tell us that the headache in these cases was due to hypermetropia or astigmatism, because they had poor acquaintance with these errors of refraction; but they observed the fact that prolonged use of the eyes on small objects gave rise to headache. The condition of the eye to which they refer was in all probability that which Stevenson, Lawrence, Sichel,† and others described about that time, and later, as *hebetudo visus*, and for which Mackenzie, in 1843, gave us the name *asthenopia*. This affection was then, as now, recognized with all its symptoms, but it remained for Donder to demonstrate, in 1858, that the accommodative form is nearly always dependent upon hypermetropia.

From this time forward we find hypermetropia mentioned as a cause of headache.

In 1869, Soelberg Wells,‡ writing on hypermetropia, expresses himself thus: "There is a feeling of tension and pain about the eye and over the eyebrow, which, if the work is persisted in, soon becomes more intense, and sometimes assumes the character of headache (which is often mistaken for nervous headache or migraine)."

Mauthner|| mentioned pain in the head as a symptom of accommodative asthenopia, in 1875.

Noyes,§ in enumerating the symptoms of hypermetropia, in 1881, said: "I have known nau-

sea to be caused, and in many hypermetropia is the cause of chronic headache."

In the same year, Harlan* said of accommodative asthenopia: "In fact the symptoms referred to the eyes may be the least prominent, or the sufferer may not even suspect his eyes at all, while the strain is manifesting itself by headache, dizziness, nausea, or nervous irritability, to such an extent as to excite apprehensions of serious disease of the brain." These quotations are presented to show that the connection between headache and those forms of eye diseases which are dependent upon optical objects has been recognized for at least fifty years, rather than to indicate the present state of our knowledge; and the last two were selected from among others to show that the subject has been mentioned in books written for the use of the general practitioner rather than the specialist.

Among those who are familiar with the use of the ophthalmoscope, there must be few indeed who would undertake the treatment of any case of chronic headache without first ascertaining the optical condition of the eyes.

It must be admitted then that Dr. Savage did not discover anything new in medicine. But he may object to my quotations, as he did in his second article† to the cases recorded in this journal by Dr. S. Weir Mitchell,‡ upon the ground that they do not refer to sick headache. He classes Mitchell's cases as nervous headache, without giving his own definition of sick headache, and affording his readers an opportunity of making comparisons themselves. He does, however, refer to Wood's|| description of the disease as "unobjectionable," but does not agree with him that "the predisposition for the most part, consists in debility of the stomach and a peculiar state of the nervous system which renders the brain especially sensitive to gastric irritation."

In as much as Dr. Wood placed sick headaches in the same chapter with irritation of the stomach, and gave only these two causes, it is fair to infer that when he wrote these words he recognized only that form of the disease which is dependent upon gastric derangement.

The peculiar state of the nervous system of which he speaks represents only the otherwise undefined difference between the nervous systems

of dyspeptics with sick headache and those without it, without indicating any particular morbid condition. In reality, then, his idea was that this disease was caused by irritation carried from the stomach to the brain. Immediately after this reference, Savage says: "Wood's views, as well as all others ever expressed, must be erroneous, if my doctrine is true." His doctrine is that hypermetropia and astigmatism, alone or combined, are the only causes of sick headache.

Upon the same page he tells us that in the *REPORTER* of May 6, 1882, we can "read an admirably written clinical history of the disease by Dr. Smith." This gentleman describes three forms, which are as unlike each other as any three cases of the same disease can possibly be. In the first form the prodromic symptoms all point to the stomach as the seat of disordered action; in the second, to the eyes, and in the third, to the nervous system, as is evinced by the inability of the subject to undergo any extra exertion, or change of habit for a day, without suffering. After the disease is fully developed, he notes no difference between these forms, and his description of that stage agrees fully with that given by Dr. Wood. They both give as prominent symptoms nausea, vomiting, disorders of sensation in other parts than the head, and of the special senses, especially of the eyes and ears.

Now then, besides acknowledging these symptoms as all properly belonging to sick headache, Dr. Savage tells us that "the relationship between the eyes and stomach is so intimate that when one is affected the other will sympathize, as in sick headache," and yet asserts that the cause of the disease is always in the eyes.

He would have us believe, then, that nervous sympathy flows in one direction only—from the eyes towards the stomach.

Why does he not explain the connection he has found between these organs?

He says "he will not attempt in this communication to give the relationship existing between the stomach and the eye;" and this is to be regretted, for if he had given it, he would certainly have avoided the ridiculous error into which he has fallen.

In the absence of all the teachings of physiology, the careful observation of cases of sick headache alone would direct attention to the brain as the connecting link, through which functional disturbances play either way, back and forth. In most instances the pain in the head holds an intermediate position in the succession of symptoms: if the disease appears in the gastric

form, some derangement of the stomach usually ushers it in; then comes pain in the head, and later on, the reflex symptoms.

On the other hand, if the cause is in the eyes, the first sign of an approaching attack is commonly some discomfort about these parts; then follows the headache, and, during its continuance, vomiting or other sympathetic disorder.

It is exceedingly difficult to understand how Dr. Savage can reconcile Wood's or Smith's account of the disease with his theory of its causation. If the disease begins in one case with irritation of the stomach, which extends to the brain and is thence reflected to the eyes; begins in another in the eyes, is transmitted to the brain and from there affects the functions of the stomach; and in a third, has its origin in uterine disturbance with spinal irritation, of which the effects extend to the brain (giving rise to headache), and thence disorder both stomach and eyes; does it not seem probable that the cause and origin may lie in any of these organs, seeing that they may be interchangeably the starting and ending place of the morbid process.

As belonging to the third order here mentioned, the following case may be presented: Mrs. — consulted me in 1873 for, (as she put it), "weakness, headache and womb disease."

She was anæmic, debilitated, suffered with sick headache once in about two weeks, and her uterus was prolapsed in the first degree. A properly adjusted pessary, with iron, quinine and belladonna restored her health after several months' treatment.

During the next five years she came under my care several times for the same symptoms, excepting the displacement of the uterus which had been permanently remedied.

In August, 1878, at which time she had one of the breaks in health, the following note was made of her headache: She has been troubled with the headache again since the warm weather set in. At times she has two attacks in one week, each lasting a day, or longer; then, again, she may be free from it several weeks. Upon going from home a day, she is pretty sure to suffer. Irregularity in habits, especially in taking meals, is apt to be followed by a paroxysm, as when a meal is taken late and the stomach becomes very empty. Sometimes it appears without any discoverable cause. It does not seem to be influenced by menstruation. When caused by emptiness of the stomach, it comes on during the fast, and is aggravated severely by taking food or drink; if vomiting then supervenes, as it often does, it

brings relief. The "sick headache" is the most frequent, but she also gets a form that is not accompanied by sickness at the stomach, and is not as intense, but continues longer than the other. In this form the pain is usually worse in the forehead, equal on both sides, while in the gastric form it is confined to one spot in the right temple. In both forms it is of a dull aching or rolling character; in the gastric, so severe that she cannot lie down or keep quiet in any position, while in the other, rest and quietude afford alleviation.

The hands and feet are cold during the paroxysms in both forms, and the face is pale. Since the return of the headache and debility she has had much dull aching pain in the eyeballs, as in former periods of ill-health. There is slight hyperaesthesia of the retina; and she says the lids feel heavy, which is owing to blepharitis marginalis. $V = \frac{2}{3}\%$. The fundi oculi are normal, as is also the refraction. She came to town this morning, and after seeing me, spent the day with friends. On her way to the cars toward evening she stopped in again and requested me to give her something to relieve a terrible headache she was suffering, and which she feared would prevent her reaching the railroad and home to-day.

She described the pain as dull, heavy and rolling with each motion of the head, most intense in the forehead. The face was deathly pale, and the hands cold. There was intense nausea, which appeared only after the pain became very severe. She was given $\frac{1}{200}$ gr. of sulphate atropia, and ordered to repeat the dose every half hour until relieved or until dryness of the throat and dilatation of the pupil would appear. At her next visit she reported that the second dose was unnecessary, and that the headache disappeared before she reached the depot.

A course of tonic medication directed to the nervous system restored her to health and freedom from headache again.

This case may be said to present two types of headache—the *sick* and the *nervous*, but in reality they are the same thing. The sick is only a further development of the nervous, as is shown by the fact that the vomiting appears only after some continuance and increased intensity of the pain. The same observation is applicable to a very large percentage of all paroxysms of this disease—they begin as nervous and end as sick headache.

This case is one among many similar ones I might cite in proof that sick headache is not always traceable to optical defects. Although there was well marked distress about the eyes, the most

careful examination failed to reveal any error of refraction, and the thoroughness of the examination is attested by the result of treatment addressed to other parts of the body. It presents an interesting feature also, as viewed with Dr. Savage's observation, that the application of atropia to his eyes stopped the headache immediately, in the very remarkable effect which the small dose of atropia manifested. I have seen this happy result follow the use of small doses of atropia and belladonna in certain forms of sick headache so often, without paresis of the accommodation, that I cannot help thinking it is produced without any accompanying action on the ciliary muscle.

In Dr. Savage's case the headache was undoubtedly due to accommodative asthenopia, dependent upon hypermetropia and astigmatism, and the charming effect of the atropia was in all probability due to its direct action on the ciliary muscle.

Now then, after having thus examined Dr. Savage's claim, and the articles to which he refers I have come to these conclusions:

1. That Dr. Savage did not discover the causative relation which optical defects hold to sick headache.
2. That, although optical defects do give rise to sick headache, they are not its sole cause.
3. That the experience of the profession warrants the assertion that, while optical defects give rise to various kinds of head pains, the severe form denominated as sick headache cannot be ascribed to them as frequently as others.

Dr. Savage deserves credit, however, for having directed attention to the carelessness of authors of works on "Practice of Medicine" in neglecting to mention optical defects among the causes of sick headache. He might with propriety have included also writers of monographs on this disease, at least all those whose works I have seen.

This method of using belladonna is not original with me; nor is it with our eminent modern therapeutists, Bartholow, Ringer, and others. We have all borrowed it, upon our own easy terms, from our erring and wayward homœopathic brethren.

STATISTIC AND ALLIED FEATURES OF DIPHTHERIA.

BY THOS. S. SOZINSKEY, M. D., PH. D.,
of Philadelphia.

THE GRAVITY OF THE DISEASE.

The serious form of sore throat, which the Capadocian physician, Aretæus, who flourished about the end of the first century of our era, tells

us was common, in his time, in Syria and Egypt, is generally held (with barely enough reason, I think,) to be really the disease first fully described by Bretonneau, a physician of Tours, in 1826, under the name of diphtherite, or as it is usually called among us, diphtheria. Many of the grievous scourges which have prevailed again and again down through the centuries, of which more or less record remains, are supposed to be none other than it. However, it is certain that in modern times diphtheria has, in epidemic outbreaks and otherwise, destroyed a shocking number of lives. Of late it has taken a leading position among pestilences. It perhaps outranks scarlet fever in the extent of its ravages among the young. In Philadelphia its victims numbered over 700 in 1876, and still far more in the year just ended (915); and in no year of late have there been less than 300. Evidently it is a very formidable disease.

It is more than probable that the disease has been proving more destructive to life within a few years than formerly; statistics from almost all quarters show this only too plainly. Its increased destructiveness is very evident in Philadelphia. From 1860 until 1875 the number of deaths in this city was, on the average, less than 250 (237) yearly; while since then it has been more than twice as great (538). During the last two months of 1882 the deaths from it numbered five or six daily.

The cause or causes of the lamentable increased destructiveness of the disease should, I need hardly say, be carefully sought for. Is there anything besides a wider diffusion of the contagion at play to produce the increase? In the case of Philadelphia, has there been a change in the sanitary conditions favorable to the disease? Has the disease become more virulent? Has there been developing a greater susceptibility to it? Do those attacked succumb more readily now than formerly?

THE AGE OF THE VICTIMS OF THE DISEASE.

In an article on diphtheria published a few weeks ago, a reputable writer states that the disease is just as serious in a person fifteen years old as in one of as many months. Of course, this statement is absurdly untrue. The disease is essentially one of infancy and childhood, so far as fatality is concerned.

Dr. Bristowe says, in his work on the "Practice of Medicine," that it is "far more common among young children, especially between the ages of three and six, than in persons of more mature age, and is both actually and relatively much more fatal to them." This may be said to be the cur-

rent opinion. According, however, to the United States census returns for the year ending June 30, 1870, most deaths are of infants; and the number steadily decreases from year to year. Thus in the first year of life the deaths reported were 1,011; in the second, 998; in the third, 791; in the fourth, 736; in the fifth, 549; in the period from the fifth to the tenth, 1,299; in the period from the tenth to the fifteenth, 335; and in the period from the fifteenth to the twentieth, 141. In Philadelphia there are nearly three times as many deaths of children in their second year as in their first; and the deaths of persons over fifteen are few.

THE SEX OF THE VICTIMS OF THE DISEASE.

There is excellent reason for believing that in general the female sex is the more favorable to the mastery of the disease. Statistics seem to show that considerably more females than males die from it. Very early in life, however, this is not the case. According to the census figures there were in the first year of life 546 males to 465 females; in the second, 535 males to 463 females; in the third, 431 males to 360 females; in the fourth, 343 males to 393 females; in the fifth, 263 males to 286 females; in the period from the fifth to the tenth, 517 males to 728 females; and in the period from the tenth to the fifteenth, 125 males to 210 females. Hence, it would appear that it is only from the third year forward that the deaths of females are in excess; before that time males succumb in greater number. It is worth while, however, to bear in mind that in the first year or two of life there is a small percentage more male than female children. Philadelphia statistics, unfortunately, are so compiled that little light is afforded by them, as to the relation between sex and disease.

HAS THE DISEASE CYCLICAL PHASES?

The study of the statistics of the mortality in Philadelphia brings to light a strange tendency of diphtheria to run in cycles of intensity, the period being six years. The following table indicates this clearly:

Date.	No. of Deaths.	Date	No. of Deaths.
1860	307	1872	150
1861	502	1873	110
1862	325	1874	181
1863	434	1875	656
1864	357	1876	708
1865	260	1877	458
1866	192	1878	468
1867	119	1879	321
1868	119	1880	323
1869	182	1881	457
1870	172	1882	915
1871	145		

It is likely because of the fact that the disease prevails most markedly in the colder half of the year that the period of maximum cyclical intensity seems to last each time two years. For some reason or reasons, then, there is every sixth year an excess of persons very liable to contract the disease, and possibly, also, very liable to succumb to it. Either this, or it must be assumed that the disease becomes more virulent, that the "epidemic influence" becomes more decided—to use a phrase employed by writers who still cling to the old-fashioned way of referring diseases to mysterious causes.

RELATIONS OF SEASON AND WEATHER TO THE DISEASE.

But little intelligent attention has been given to the special atmospheric conditions which are promotive of the spread of diphtheria or otherwise. Most writers on medicine who refer to the matter at all make rather amazing statements. Thus, Dr. Roberts, in his work on the "Practice of Medicine," says: "Hot and dry climates and seasons appear to favor the development of the poison-germ." The doctor would not have expressed such an opinion if he had taken pains to learn anything about the matter. Had he turned to the well-known studies of Mr. Buchan and Dr. Mitchell, he would have found that in England the disease is most prevalent "in cold, moist weather." I advise the reader, however, by the way, to avoid the common mistake of taking the Englishman's "cold" and "warm" as synonymous with what we call "cold" and "warm."

As I have already stated, it is in the colder half of the year that diphtheria is most prevalent. During the 14 years ending with 1881, there were in Philadelphia, in the first quarter, 1179 deaths; in the second, 940; in the third, 792; and in the fourth, 1519. According to these figures there were nearly twice as many deaths during the fourth as during the preceding quarter. Not far from two-thirds occur in the colder half of the year. A similar statement holds good in reference to the returns of the census (3,627 to 2,673). This greater winter prevalence is common, I think, to all contagious diseases. The cause is likely, to some extent at least, the better chance for the virus to take effect, because of crowding and bad ventilation. Cold in itself should not be favorable to the spread of contagion, for it serves to lessen and stop activity in matter, both organized and unorganized. Nor indeed is it in the very cold any more than in the very warm weather that contagious diseases are apt to be most prevalent.

In Philadelphia, moderately cold, damp weather

is the most favorable to the spread of diphtheria. Or rather, I believe, I should say, the change to such weather. A fall in the temperature to from 60° to 50°, and an increase in the average daily humidity to from 70 to 75 or over, will very certainly be followed by a decided increase in the number of cases. Of course, then, an increased mortality may be expected toward the beginning of November. The general absence of sufficient preparation for such vicissitudes of atmosphere as are usually met with toward the end of October and in November, and the segregation of population which they produce, are evidently potent indirect causes of the prevalence of the disease. Weather which has been regarded time out of mind as favorable to the production of catarrhs, is the weather which is most favorable to diphtheria.

I have hinted above that very cold weather is not very favorable to diphtheria. A somewhat prolonged spell of cold weather, weather below the freezing point, tends greatly to extinguish the disease. This was markedly observable in Philadelphia in January and February, 1875, in January, 1876, and in December 1881.

A decided rise of temperature, especially if sudden, in the colder half of the year, increases the cases of the disease. With the spell of oppressive warm weather which is usual in Philadelphia in May, there is almost certain to be an attendant decided increase in the mortality from the disease. This was very noticeable in 1875 and in 1877, years in which the spell was very marked.

I have seen a statement to the effect that a heavy rainfall may cause an increase in the disease; but there is little or no ground for such a belief. If there be a heavy rainfall at any time during the last quarter of the year, an increase in the mortality may follow, but it will depend on the temperature and the humidity. Thus, in the second week of November, 1877, there was a heavy precipitation followed by a great increase in the mortality; but the temperature was declining towards 50° and the humidity was rising above 70. On the other hand, there was a heavy precipitation in the fourth week of November, 1876, but there was no evident consecutive increase in the mortality. The temperature was low, and hence unfavorable. In a large city, at least, a heavy rainfall should tend to prevent the spread of the disease, if there be any truth in the notion that it springs largely from dirt. This would appear to be the case sometimes, especially in the warmer part of the year, as in June, 1881, in Philadelphia.

It would be easier to trace a connection between a marked absence of precipitation and the prevalence of diphtheria than the reverse. Thus toward the end of December, 1877, there was a great rise in the rate of mortality in Philadelphia—a month in which there was no precipitation, save a little in the first week of it. But during that month the humidity and the temperature were both unusually high. In December, 1882, there was little rainfall and a very heavy mortality, but the weather was much warmer than usual, and humid.

It would not be hard to trace a connection between the prevalence of the disease and the direction of the wind in Philadelphia. When the temperature is at a moderate figure, and the wind blows from the east, northeast, or even the north, the condition is favorable to diphtheria. Such winds are generally attended with a high state of humidity of the air.

HOW TO PREVENT THE DISEASE.

It is safe to say that the vast majority of the cases of diphtheria, properly so-called, are due directly to contagion, that is, a virus generated in the system of a person affected with the disease. In fact the cases which are produced otherwise, if at all, are exceptional, I believe. Sore throats of various degrees of severity may be greatly multiplied by bad drainage, sewage exhalations, and filth generally; and no doubt these are often said by the incompetent or knavish practitioner to be cases of the alarming disease. I can readily believe that sewage exhalations and unsanitary conditions of all sorts may tend to produce a pronounced susceptibility to the disease, and to render the system little able to resist it when present; but I can find no solid reason for the opinion (of Dr. Snow and others) that it is perhaps always due to "impure air or impure water," that if cases exist in a house it is "proof positive that the causes of the disease exist in the house." This notion seems childish in view of facts like these:

In 1875 the victims of the disease in Philadelphia were from three to four times as many as in any of many years before. In that year the deaths in the 21st ward (an outer one, the one in which the town of Manayunk is situated) of that city were out of all proportion to what they were in any other of the 29; they were 72, or one to every 237 of the population—five or six times more than in most of the others. In 1876 they were still more than in any of the other wards, as might be expected from the continuance of the epidemic over from the last quarter of the preceding year.

The deaths in the ward in 1877 were 7; in 1878 they were 2; in 1879 they were 6; in 1880 they were 8; and in 1881 they were 6—less for any year than in very many of the others. The 27th was the ward which had the smallest proportion of deaths in 1875, there being 4, or 1 to 5614 of the population. Now, in 1878, the year in which the mortality was lowest in the 21st, the rate in it was far higher than in the majority of the others, there being 19 deaths.

A general recognition of the truth that any case of diphtheria worthy of the name is decidedly contagious, is something greatly to be wished for by every philanthropic member of society, because the recognition of it has a vital connection with the supremely-important matter of the prevention of the spread of the disease.

While not neglecting the sanitary conditions, it is the contagion to which the practical sanitarian should principally give his attention, if he would restrict and suppress diphtheria. In a recent report to the National Board of Health, Dr. Elisha Harris says; "The infection and propagating cause of diphtheria is the one essential cause which sanitary science lays hold upon to arrest and to prevent its epidemic prevalence." Dr. H. B. Baker and almost all other competent sanitarians are also of that opinion.

The American Public Health Association, at its meeting in New Orleans, in December, 1880, in connection with a resolution that "the contagiousness of diphtheria is now well established," resolved that the disease "should in all cases be treated with the same rigorous isolation and quarantine that is everywhere enforced against small-pox."

There is a crying need in Philadelphia and many other communities for the institution of the rigid isolation plan of prevention of disease. Why it is not brought into play to any great extent is unaccountable. Health authorities that have the power to apply it, and do not, may be justly blamed for much of the great suffering and lamentable mortality from the disease. It is a horrible outrage on a community to let anything possible be left undone by organized authority which will check the spread of a deadly contagion. It is not interfering improperly with the just rights of any one affected with a contagious disease to isolate him. His wish should not rule in the case. He might be destroying life right and and left without being conscious of it. A young man affected unmistakably with diphtheria went to a crowded church the other day, and did not realize, although told, that he was committing a

terrible crime against his fellow-men. The intelligent part of a community, which is surely the greater, should see to it in an official way that every one affected with a serious contagious disease is duly isolated, and that disinfectants and fire are duly brought into play to extinguish the contagion regardless of cost. Doubtless all honorable physicians would be glad to have an authoritative inspector to enforce proper sanitary precautions in every case.

The plan of dealing with diphtheria and other grave zymotic diseases indicated, is both sound and politic, and it is practicable too. Through a special hospital, a corps of sanitary inspectors, and the enforcement of a law requiring all practitioners of medicine to immediately report the cases met with by them, the malign power of diphtheria might be overcome, and the perennial destruction of children now tolerated be almost entirely prevented.

The right way to deal with diphtheria or any other contagious disease is precisely the way leprosy was dealt with long, long ago, namely: isolate each and every case, and through cleansing and disinfecting processes, and a discriminating resort to fire, extinguish the contagion. It is all explained in Leviticus. When a person became affected with leprosy he was declared unclean, and then the rule in application was: "He shall dwell alone; without the camp shall his habitation be." The clothing used by him was cleansed and disinfected or burned, and his place of residence subjected to thorough purification, or destroyed entirely.

In damp, moderately cold, changing weather, special care should be exercised not to experience disturbances of the system, if one would keep himself little susceptible to the disease. Especially should children be protected; and, of course, very special care should be exercised when the disease is prevailing extensively.

Weakness seems to greatly favor the disease. In adults it is generally light. Females suffer more from it than males from the third year of life forward—the greater life-force in boys becoming apparent after that age, the mode of life likely doing much to produce it. Let the strength be specially supported, then, when the disease is prevailing; for it will not only favor escape from it, but recovery from it if contracted.

—A case of real leprosy exists in Salem, Mass. The patient contracted the disease in the Sandwich Islands seven years ago, and it is approaching a fatal termination.

HOSPITAL REPORTS.

ON POST-MORTEM EXAMINATIONS OF THE BRAIN.*

DELIVERED BEFORE THE MEDICAL CLASS OF THE UNIVERSITY OF PENNSYLVANIA,

BY CHARLES K. MILLS, M. D.,

Neurologist to the Philadelphia Hospital, and Lecturer on Mental Diseases and Electro-Therapeutics in the University of Pennsylvania.

Lecture 1.

Reported by WILLIAM H. MORRISON, M. D..

GENTLEMEN:—I have here a body with the brain in the skull, and also brains which have been removed, and shall to-day lecture to you on the post-mortem examination of the brain.

Very little attention is, as a rule, paid by physicians to the study of the proper methods of examining the brain, although this subject is one of great practical importance, and much may be learned by such examinations if carefully conducted.

If possible, you should always have a number of keen-edged knives of various lengths. One should be long enough to slice entire hemispheres, and one should be small enough to pass through the foramen of Monroe. The knives when being used should be wet from time to time, preferably with alcohol.

The incision through the scalp should be made from within outwards, in order to prevent mutilation of the hair. The temporal muscles should be left in position, as a few stitches through them will assist subsequently in holding the skull-cap in position.

You should, when possible, make certain skull measurements as you proceed. Several methods of making these measurements have been recommended. One of the best of these is that of Wight.† In this method, the mastoid processes are taken as the points of departure; and the measurements are made from the middle of the process, just back of the auditory meatus, ordinarily from half an inch to an inch above the mastoid extremity. This point is nearly in a line with the base of the cerebrum, but it is a little below the insertion of the tentorium, so that some of the cerebellum may rise above this point. Having located these points, the measurements are made in the following directions from one mastoid process to the other:

- (1) An anterior arch, just above the supra-orbital ridge.
- (2) A frontal arch, over the frontal eminences.

*In the Philadelphia *Medical Times* for April 24, 1880, was published a lecture "On the Post-mortem Examinations of the Brain," delivered by me before the Philadelphia County Medical Society, February 11, 1880. This I have freely used in the preparation of these lectures. Dr. S. T. Cleverger published in the *Journal of Nervous and Mental Diseases* for October, 1879, a paper on the same subject; and a valuable work on "The Human Brain; Histological and Coarse Methods of Research," by W. Bevan Lewis, of the West Riding Lunatic Asylum, has just appeared. From these sources, and from the works of Ecker, Virchow, Charcot, Richet, Ferrier, Bitot, Delafield, Orth, Holden, and others, material has been obtained.

†Some Measurements of Skulls and Heads, etc., monograph by J. S. Wight, M. D., of Brooklyn, N. Y.

(3) A middle arch nearly over the coronal suture. In better developed skulls and heads, the coronal suture is further forward; in less developed skulls and heads, the coronal suture is further backward.

(4) A superior arch, nearly over the vertex and about parallel with the axis of the foramen magnum.

(5) A posterior arch, over the occipital protuberance, nearly on a line with the insertion of the tentorium. These are the inter-mastoid arches.

In addition, the following should also be taken:

(6) A diametrical base line from one mastoid process to the other.

(7) The greatest transverse diameter.

(8) The greatest antero-posterior diameter—leaving out the frontal sinuses.

(9) The greatest antero-posterior circumference—leaving out the frontal sinuses and measuring somewhat above the occipital protuberance.

(10) The masto-frontal angle, which is included between the plane of the anterior and superior arches.

In sawing through the skull, the cut should not be exactly circular, but should be wedge shaped, either in front or behind. The old plan was to make the wedge posteriorly, but I think that it is better to make it anteriorly. This causes the bones to fit together more neatly than when the cut is a simple circle. The bones should not be sawed entirely through, but the section should be finished with the chisel, mallet and hook. In this way injury to the meninges and brain is avoided. If possible, the dura mater should be left intact. A certain amount of adhesion of the dura mater to the skull is usually found, but a sharp pull with the hook is usually sufficient to separate the skull-cap from the dura mater. If the adhesions are great, you should carefully separate them by the knife and fingers. According to my experience, the greatest amount of normal adhesion is found in the very old and in the very young, while the least is found in youth and middle life. It is important to bear this point in mind in making post-mortem examinations in young children, say from one to three years old, for at this age the brain is less consistent than it is later in life, and a sharp pull on the skull-cap may tear the brain to pieces. A good plan in such cases, is after the skull-cap has been thoroughly loosened with the saw and the chisel, to slit the dura mater in the line of the saw and remove it with the skull-cap. In the subject on the table, evidently a real external pachymeningitis has been present, for the dura mater was everywhere strongly adherent to the inner surface of the skull.

Having removed the skull-cap it should be carefully examined, and the thickness of the skull in definite localities should be noted. The exact position of the cut should be observed, for, as you can see, the thickness of the skull will vary greatly according to the position of this section. The measurements of thickness should be described as having been made at certain parts of the frontal, parietal, temporal and occipital bones. The inner surface of the bone should now be examined for abnormal conditions, such as caries and exostoses.

The external surface of the dura mater presents

many things for minute examination. In the first place, you may have evidences of pachymeningitis. If this has been recent, everywhere the evidences of inflammation will be noticeable—redness, swelling, infiltration, etc.; if old, pus may be found between the dura mater and the skull, or you may have thickening, induration, or concretions. Syphilitic disease of the external surface of the dura mater may also be found, although syphilitic tumors are most frequently found beneath the dura mater or pia mater.

Extravasations of blood may be present between the dura and the bone: and as I myself have seen, the bone itself may be soaked with blood.

Before proceeding further, the longitudinal sinus may now be carefully examined. The other sinuses may be left until after the removal of the brain. The examination of these venous channels is often omitted; but nothing is more important. The longitudinal sinus should be laid open, preferably with a scalpel or bistoury, from before backwards. You look first for thrombi. In cerebral disease thrombi are frequently found, and even when disease of the brain is absent, thrombi may form in the act of death. Evidences of phlebitis, thickening, deposits, etc., should be sought for. The condition of a thrombus, as to organization, its size and site, should be determined. The association of phlebitis with caries, or other disease of the bone, should be investigated.

Having done this, you next sever the dura mater from its anterior connection with the crista galli. This is done by lifting up the dura with the fingers or forceps until the point of junction is reached, and severing the falx at its anterior extremity with a knife. The scalpel is then inserted to one side of the longitudinal sinus, and an incision made in the line of the saw and carried backwards to the tentorium. A similar incision is made on the opposite side. The convexity of the dura, with the falx, are then carefully detached by pulling and dissecting.

Finally all the attachments between the under surface of the cerebrum and tentorium are separated. The brain covered by the pia mater is now exposed. This surface should now be examined, for important signs may now be present which will entirely disappear in the further process of removal of the brain. Oedema may be present. It is a very common condition in the brains of the insane and in senile atrophy, and one which will very probably disappear during the removal of the brain from the skull. If the pia mater and arachnoid have been left intact, the amount of the fluid, its character and its position, can be determined. In order to do this, you must have a correct understanding of the membranes and the spaces between them; but before speaking of these, I wish to say a word about the paccchionian bodies or granulations.

The paccchionian granulations are apt to give trouble to the tryo. These are little granular bodies found on the convex surface of the brain, most numerous along the longitudinal sinus. It has been recently stated that they have some connection with the veins of the membranes of the brain. Sometimes they run together, forming masses from three to six inches in length. This is not necessarily an evidence of meningeal dis-

ease. There may be a great normal development of these bodies. You should, however, note every point just as it exists. Do not suppose that you have meningitis with exudation simply because you have exuberant pachionian granulations.

Let me now make a few remarks in reference to the membranes and spaces which, as I have said, must be understood in order to make a satisfactory examination. The brain has three membranes, the dura mater, the arachnoid, and the pia mater, although some authorities do not regard the arachnoid as a distinct membrane. One layer of the arachnoid, the parietal, lines the inner surface of the dura mater, while the other, the visceral, covers the outer surface of the pia mater. You are, no doubt, familiar with the two spaces ordinarily described, *i. e.*, the arachnoid and the sub-arachnoid space; but there are really four spaces to be studied in making these examinations. These are, in addition to the two just mentioned, the sub-dural and the epi-cerebral spaces. The arachnoid space is that familiar to you as the space between the parietal and visceral layers of the arachnoid, or between the internal arachnoid surface of the dura mater and the external arachnoid surface of the pia mater. The sub-arachnoid space is that beneath the visceral layer of the arachnoid. It is formed by this layer jumping the fissures and the spaces at the base of the brain. By a simple incision, I open this space in the position of the fissure of Sylvius. The visceral layer of the arachnoid does not directly bridge the longitudinal fissure from one hemisphere to the other, but it first descends to just beneath the falx, and then crosses the longitudinal fissure. When the dissection is carefully made, this can be seen. In this sub-arachnoid space there is found normally a certain amount of the cerebro-spinal fluid, but if atrophy of the brain has taken place, there may be an immense amount of this fluid. If it is desired to know the amount of liquid in the ventricles, now is the time to determine it. Make a small incision into the ventricle from above through the longitudinal fissure, insert the nozzle of a syringe, and withdraw the fluid. Of the other two spaces which should be remembered, the sub-dural is between the dura mater and the parietal layer of the arachnoid. It is a practical space, because it can be injected. In hæmatoma of the dura mater, the existence of this space may become evident. The other, the epi-cerebral space, is nothing more or less than the space between the pia mater and the naked brain substance. In atrophy of the brain, the whole pia mater may be lifted up, and there will be effusion, not only into the sub-arachnoid space, but also into the epi-cerebral space. Variations in the amount and quality of the cerebro-spinal fluid, pachymeningitis, clots, coagula, opacities, deposits, and adhesions of the membranes, should be noted.

We are now ready to remove the brain itself. If the dura mater of the convexity has been removed in the way that I have described, the brain may be quickly taken out. The brain should be thoroughly supported on all sides. Tilt the organ a little backwards, and proceed to sever the nerves and vessels. The optic nerves are first cut, then comes into view the infundibulum, then the vessels appear. In cutting nerves and vessels, al-

ways do so as far as possible from the brain. If it is desired, the pituitary body may, by a little dissection, be removed intact. After severing the third and fourth pairs of nerves, I come to the tentorium. I make an incision through the tentorium on each side along the lateral sinuses. This exposes the cerebellum on each side. With these two cuts, everything is free as far as membranes are concerned. I now divide the remaining nerves and vessels. Passing a knife down as low as possible, I sever the spinal cord. The brain is now withdrawn from the skull without the slightest difficulty.

The floor of the skull should be carefully examined, the neighborhood of the foramen magnum and the sella turcica receiving special attention. It is often important to examine the Casserian ganglion, and the portions of the cranial nerves remaining behind in the skull grooves and cavities. Deformities of the internal surface of the skull should be looked for. One of the most common seats of intra-cranial syphilitic disease is near the petrous portion of the temporal bone. The ethmoidal region should also receive close attention.

The remaining sinuses require careful examination. Beginning at the torcular herophili, each sinus should be opened and examined in the same manner as was the longitudinal.

The internal surface of the dura mater is to be examined for deposits, thickening, or other abnormal appearances. In some forms of pachymeningitis the dura mater is very thick; in hydrocephalus and hypertrophy of the brain, sometimes very thin. In internal pachymeningitis, the inflammation, curiously enough, is likely to involve certain areas which correspond pretty accurately with the parietal bones. Well marked thickening, even to the extent of one-tenth or one-eighth of an inch, or more, is sometimes found.

Next proceed with the base of the brain upwards to a further examination. A good method, and the natural one, is to place the brain in the skull-cap. There it will fit most accurately, and enable you to study the parts most conveniently and most nearly in position.

The pia mater of the base is to be examined for evidences of inflammation, effusion, and the like. Do not be misled into recording that there is congestion here or elsewhere in the pia mater, or in the brain substance, when there is no real congestion. The veins are often filled with blood without any real congestion; or there may be a hypostatic congestion. True hyperæmia will show itself by staining, and appearances not removable by water or ordinary handling. Following Niemeyer, we should make it a rule to consider hyperæmia of the cerebral membranes as proved only in those cases where the finest vessels as well as the veins are injected, and where the overloading of the cerebral vessels is not at all in proportion to the amount of blood in other organs.

The vessels at the base of the brain are to be examined with care. The arrangement of the vessels forming the circle of Willis, is to be noted. Here is the circle of Willis, removed by Dr. Elder. As you know, the vertebral arteries pass up and unite to form the basilar. This gives off the posterior communicating arteries which pass forward and join the carotids. The anterior and middle cerebral arteries are then given off—the latter

going to the fissures of Sylvius. The anterior cerebrals are joined by means of the cross branch, the anterior communicating artery. We are indebted to Heubner and Duret for much of our knowledge of the blood supply to the brain, while Charcot has paid special attention to the lesions arising from hemorrhages, embolisms, softenings, etc.

A few words about the distribution of the branches of the circle of Willis may prove of value.

The anterior cerebral artery passes over the median surface, runs backward over the corpus callosum, and anastomoses to some extent with the branches of the posterior cerebral. It gives off branches which supply the orbital lobe, the convolution of the corpus callosum, first and second frontal convolutions, paracentral convolution and præcuneus. The middle cerebral or sylvian artery divides into four principal branches. The first of these has been called, by Duret, the frontal external and inferior. It supplies chiefly the third frontal convolution, and many instances of aphasia from its obliteration are on record. The second branch is the artery of the ascending frontal convolution. The third branch is the artery of the ascending parietal convolution, or posterior Rolandic lobule. The fourth branch supplies the gyrus angularis and superior temporal lobule.

Softenings in the regions supplied by these arteries produce consequences consistent with the function of each part. Disease of the ascending convolutions has been followed by paralysis, etc.

The middle cerebral is most frequently the seat of serious alteration.

I glance at the distributions of these vessels, because knowledge of this kind will assist you in seeking out lesions of the arteries. Having certain symptoms during life, you will, by preference, at once look to certain regions for softening, clots, etc.; or, again, having discovered a certain lesion in your examination, an area of softening, for instance, you will know what vessels to follow in searching for the cause of the lesions.

The examination of the arteries, and of the entire brain, will be facilitated by the use of a hand lens.

The color of the vessels should be noted. They should be examined for dilatations, of various kinds, for aneurisms, dilatations from embolism and thrombosis, and from syphilitic and tubercular disease. These can be readily determined by the naked eye. Twistings and kinks in the vessels should be looked for. These have sometimes great pathological significance. Kinks of the larger vessels are sometimes found as a normal peculiarity, but if, on examination, you find that the vessels throughout the brain present a great many little kinks, it means that the brain has been frequently congested, and that the spaces around the vessels have allowed the kinking to take place, and that this has afterwards remained as a pathological condition. The coats of the vessels should be examined for evidences of atheroma. The condition of the nutrient vessels is to be carefully observed. This is frequently omitted. These are vessels which pass from the under surface of the larger arteries and dip into and supply the interior of the brain. Lifting up the vessels at the base of the brain, it will be found that through the anterior perforated space dip down a large

number of straight vessels, supplying chiefly the corpora striata; through the posterior perforated space dip vessels supplying the optic thalami and their surroundings; and from the basilar artery vessels going to the pons. These vessels are sometimes diseased, and some of them are the chief seats of cerebral hemorrhage.

Having examined the vessels in position, they should be removed for preservation or further examination. This is to be done by cutting the vessels beyond the point at which the main vessels of the circle of Willis divide into branches, and drawing out the nutrient vessels and removing as much of each one as is possible. I have dwelt upon the examination of the vessels, as it is very important.

The next thing to be done is the removal of the pia mater. The pia mater has a certain normal amount of adhesion to the brain, in which a little but not marked difficulty in removing the membrane is experienced. The membrane sometimes strips off with the utmost ease. This always indicates a diseased condition, usually atrophy of the convolutions, with effusion of liquid between the pia mater and the brain, or the latter without atrophy. The membrane may be abnormally adherent. This is usually an evidence of inflammation, and even where there is no thickening or exudation, this abnormal adhesion may be present. This was the case in certain regions of Guiteau's brain. In these cases, drawing on the pia mater may detach little particles of the convolutions. The removal of the pia mater can be done under water, but, as Ecker points out, the stay of the brain in the water must be limited; it otherwise becomes too soft by imbibition. The operation can usually be readily accomplished out of the water. With a pair of fine forceps in each hand, the membrane and its vessels can be pulled out of any convenient sulcus, and adjoining convolutions uncovered. The finger can often be advantageously substituted for the forceps. It is not always necessary to remove the whole of the pia mater, but for a thorough post-mortem examination, the entire brain should be uncovered.

Before proceeding to examine the convolutions and the interior of the brain, I shall indicate to you the methods of determining the volume of the brain, its specific gravity, and the cranial capacity.* These operations can be performed in a short time, and often give important information. The brain should first be accurately weighed.

Dr. Hack Tuke's method of determining the volume of the brain is based on the Archimedeian principle of displacement. This observer used a vessel of convenient size and shape, with a capacious spout placed at an acute angle with its sides. Water is poured into this vessel up to the level of the spout. Fluid contained in the ventricles of the brain and sub-arachnoid space is allowed to escape by several long incisions: and then the brain, including the medulla oblongata, is gradually immersed, the displaced water, as it escapes from the spout, being caught and measured, affording an exact criterion of the actual bulk of the brain.

*These methods are given from Dr. W. Bevan Lewis' monograph on "The Human Brain: Histological and Course Methods of Research."

The next thing to be done is, to determine the cranial capacity, so that you may compare it with the volume of the brain. There are several methods of doing this. One is to fill the skull with flaxseed, and measure the quantity employed.

The plan used by Dr. Hack Tuke is as follows: The foramina at the base of the brain are plugged with tenacious clay—that used by statuary for modeling answers best; a small triangular piece is removed from the frontal bone; the calvarium is readjusted to the base, the dura mater being left attached. The space left by the saw in removing the calvarium is filled with clay, and a narrow bandage with clay spread upon it is made to surround the cranium three or four times, covering this space. If this has been carefully done, the cavity of the cranium will be found as tight as a bottle. Sixty fluid ounces of water having been measured, a sufficient quantity to fill it is now poured into it, by means of a funnel, through the orifice in the frontal bone, taking care that the stream does not wash away the luting of the foramina. The fluid which remains after having filled the cranial cavity is measured, and being deducted from the sixty ounces, gives the amount employed. To this must be added half an ounce for the space occupied by the luting.

The paraffin method, adopted by W. Bevan Lewis, may be described as follows: Fill up the foramina at the base as previously described. A triangular or wedge-shaped piece is now sawed out of the occipital bone, after removal of the calvarium, but retained in situ. The base is then filled with melted paraffin, the skull-cap replaced and retained by luting, as in the previous method, having previously trephined a piece out of the frontal bone. Through the latter orifice more of the paraffin is poured in, until the cranial cavity is filled. When cool and solid, remove the calvarium as well as the wedge-shaped piece of bone from the occiput, and then gentle pressure from behind tilts the solid mass out of the cranium, when it will be found to form an exquisite mould of the interior. The mould thus obtained is to be measured by displacement, whence we obtain the cranial capacity.

The normal brain capacity is about fifteen per cent. less than the cranial capacity. The presence of hypertrophy or atrophy can thus be readily determined.

The following table of brain-weights may be of interest:

	Ounces.
Maximum weight of adult male brain . . .	65
Average weight of adult male brain . . .	49.5
Minimum weight of adult male brain . . .	34
Maximum weight of adult female brain . . .	56
Average weight of adult female brain . . .	44
Minimum weight of adult female brain . . .	31

The heaviest human brain on record weighed 67 ounces.

The specific gravity may be readily obtained by the method of Dr. Bucknill, which consists in immersing portions of the cerebrum and cerebellum in a jar of water wherein a sufficient quantity of sulphate of magnesium has been dissolved to raise the density of the fluid to the point required, adding water or a strong solution of salt until the

cerebral mass hangs suspended in the fluid, without any tendency to float or sink; and then by testing with the hydrometer, the specific gravity is thus found with great delicacy and facility, a difference of half a degree in the density of the fluid being indicated by the rise or fall of the substance immersed.

I shall postpone the examination of the surface and interior of the brain until the next lecture.

UNIVERSITY HOSPITAL.

CLINIC OF JOHN ASHHURST, JR., M. D.,

Professor of Clinical Surgery in the University of Pennsylvania.

Reported by LOUIS J. LAUTENBACH, M. D.

Case 1.—Naevus; operation by ligation.

Case 2.—Hydrocele: tapping.

Case 3.—Stricture of the rectum: syphilitic: dilatation by rectal bougies.

Case 4.—Necrosis of tibia.

Case 1. Naevus—Operation by Ligation.

This child, but a few months old, has a tumor on the top of the head, consisting of an enlargement of venous capillaries, and known as a naevus. Naevi are divided into cutaneous and sub-cutaneous, one variety of the former kind being commonly known by the name of mother's mark.

The treatment of the cutaneous naevus is much more simple than that of the sub-cutaneous variety; the best treatment consists in the application of strong nitric acid, which causes the formation of a dry slough, the part often healing without any dressing. If the naevus is sub-cutaneous, this treatment is not sufficient. For the treatment of this variety a number of measures have been proposed, of which I consider that of ligation the safest. The injection of a solution of the perchloride or persulphate of iron, I consider to be attended by considerable risk: the injection may cause the formation of a clot which is carried into the general circulation, giving rise to embolism.

The method of ligation which is adapted to flat or elongated naevi is that described by Erichsen. It consists in passing a long double ligature, stained black for half its length, in such a way as to have a series of double loops on each side of the tumor, then cutting all the black loops on one side and the white on the other. The loops are secured so as to strangle the growth in sections. In a naevus of this size, however, the above method need not be adopted, as here by the introduction of two hare-lip pins at right-angles to each other, passing immediately beneath the tumor and then strangulating it by a ligature held in place by these pins, the desired purpose is attained. This method, as you see, has been here adopted, and already the color of the tumor has greatly changed, it now having a dark blue aspect.

In passing the pins, if the tumor is situated over a fontanelle, you must be cautious not to impinge upon the membranes of the brain. The ends of the pins must be cut off so as not to injure the surrounding skin.

After the part has been strangulated for a few days, the tumor sloughs and comes away, leaving

a circular ulcer, which heals by granulation. At present we will dress the tumor with dry lint, merely to protect it from mechanical injury. When the slough begins to separate, it will be dressed by zinc ointment, or a poultice, as may be necessary.

Case 2. Hydrocele.—Tapping.

This man comes here with a tumor of the scrotum, which we recognize as a hydrocele. There is fluctuation present; there is a certain lightness in proportion to the bulk—the specific gravity is low; the tumor has a pyriform shape, and by transmitted light the tumor would be found to be translucent. Sometimes this last test fails on account of the thickness of the tunics. I remember many years ago seeing at another hospital the operation of castration performed because this test had given a negative result, the case being really one of hydrocele, in which there was opacity of the tumor, due to calcareous degeneration of the vaginal tunic. A very good way to distinguish hydrocele from hernia is by invaginating the finger, and carrying it up to the inguinal ring, which in a rupture is found to be occupied by the neck of the hernia, whereas in hydrocele it is free, and the spermatic cord can readily be felt.

In tapping a hydrocele, care must be taken in introducing the trocar and canula to avoid wounding the superficial veins or the testicle. The skin must be made tense, and the trocar inserted perpendicularly to the tumor; when it has entered the sac, which will be known by the cessation of resistance, the point of the instrument must be turned upward and the trocar withdrawn, when the fluid escapes through the canula. In withdrawing the canula, care must be taken to prevent any fluid from getting into the scrotum itself; this is done by pinching up the scrotum as we withdraw the instrument. The wound is then closed by an adhesive strip.

Our patient has already had the operation performed on three different occasions, and is not desirous of having any radical measures adopted. The treatment of this case is simply palliative, and sooner or later will have to be repeated.

Case 3. Syphilitic Stricture of Rectum.—Dilatation by Bougies.

This man has suffered for some time with stricture of the rectum, complicated with a fistula in ano, which was operated upon last summer by Dr. Wharton. It is easily understood how irritation by the fecal matter above the stricture might cause ulceration in that position, and thus give rise to fistula; but it is harder to understand how stricture gives rise to irritation and consequent ulceration below its own position; and yet this is where the internal opening of the fistula is most often found.

The explanation is that if stricture is present, the normal action of the rectum by which the last particles of fecal matter are thrown out is prevented. There is always a certain amount of fecal matter retained between the stricture and the anus, which occasions irritation and formation of abscess below the seat of stricture.

We hope to be able to relieve this patient without any serious operation, by introducing bougies, thus obtaining instrumental dilatation, just as we do in stricture of the urethra.

Sometimes in these cases the long tube of

O'Beirne is very valuable for purposes of exploration. Where it is necessary to introduce injections high up, this tube is also of special value, since it may be carried up as far as the transverse colon.

The division of a rectal stricture by the knife or *écarseur*, if the constriction is situated as far from the anus as it is in this case, is attended with great risk of opening the peritoneal cavity. This operation we will not attempt, therefore, but will confine our efforts to the use of rectal bougies, beginning with one about the size of the finger, and then following this by others of larger size. Very often in the introduction of bougies, the end strikes against the promontory of the sacrum, and on account of the resistance offered to its passage a diagnosis of stricture is made when none exists. I have not a great deal of confidence in most of the reported cases of stricture very high up; they do occur, but they are very rare. Stricture even of the small intestine has been demonstrated by post-mortem inspection, but such cases are very exceptional. Almost invariably the structure can be reached by the finger.

Our patient has a syphilitic history; he has in various parts marks of syphilitic ulceration; and I have no doubt that his stricture is due to the same cause.

The instruments which I prefer for rectal dilatation are flexible, and with bulbous or conical points. In the use of these instruments, care must be taken not to employ much force, as otherwise the rectum might be perforated. Passing now the bougies, beginning with one about the thickness of the finger and gradually increasing the size of the instruments, we can dilate the stricture as much as seems desirable. As in the case of urethral stricture, the use of the bougie must be continued at regular intervals.

Case 4. Necrosis of Tibia.

This case is an interesting one of bone disease, necrosis of the tibia, which was operated on some time ago at another hospital, but in which the disease has recurred. There are at present several sinuses to be observed, connected apparently with a large cavity in the bone.

In operations upon the bones, the Esmarch bandage is of great use in preventing loss of blood. The sinuses are covered with lint, the elastic bandage applied from below upward to a point above where the nutrient artery enters the bone, and then the rubber cord or tube adjusted.

The cicatrix of the former operation is situated above the internal malleolus. There is a sinus anteriorly, as well as one on the inner side. Making now an incision through the skin, we soon come down to a small hole, or *cloaca*, leading to dead bone. Thoroughly to lay open the cavity, we must, with a trephine or chisel, cut away the bone lying in front of it. Now cleaning out this cavity, we will see if the other sinus communicates with it, and if it does we will insert a seton through both openings. It seems, however, that this sinus communicates, not with the cavity already opened, but with another distinct cavity which extends downwards into the internal malleolus. Cleaning and scraping out this cavity also, we will stuff both of them with oiled lint, covering this with oiled silk, oakum, and a roller bandage.

COLLEGE OF PHYSICIANS, OF PHILADELPHIA.

Observations on the Management of Enteric Fever According to a Plan Based Upon the So-called Specific Treatment.

BY JAMES C. WILSON, M. D.,

Physician to the Jefferson Medical College Hospital, and to the Philadelphia Hospital.

[Read January 3, 1883.]

I desire to lay before the college a plan of managing enteric fever, which I have employed during the past year, and which, tested by such uncertain but not necessarily fallacious means as are available for a limited series of cases, has yielded satisfactory results.

The object of this communication will, I believe, be best attained by first sketching in outline the plan of treatment itself, next by reviewing the considerations which led to its adoption, and finally by a brief study of the cases. This arrangement of the topics will enable us to economize time.

The Plan of Treatment.—The scope of this paper, and the necessity to be brief, debar me from the consideration of the general management of the patient, dietetics, the treatment of complications and sequels, and of the prophylaxis, and restrict me, in the main, to the subject of the management by medicinal means. It is, in fact, this part of the treatment that, superadded to the so-called rational and expectant method in general use in this community, differs from the common practice, and constitutes the plan in question.

So soon as the patient is found to have enteric fever, or in many instances so soon as his symptoms warrant a reasonable suspicion that he is about to develop it, he is put to bed, ordered a diet consisting of milk, animal broths, jelly and simple custards, in small amounts and at intervals of two or three hours. At night he is given a dose of calomel. This dose varies in amount from $\frac{7}{8}$ to 10 grains (0.5 to 0.65 grammes) and is repeated every second evening until three or rarely four doses have been administered in the course of the first six or eight days. It is given alone or in connection with sodium bicarbonate. There is commonly a slight increase of diarrhoea, if it be present, without aggravation of the other symptoms, and in some instances the tendency of the temperature at this time to steadily rise, appears to be controlled. If, as is frequently the case, spontaneous diarrhoea has not recurred in the first week, the calomel usually brings about two or three large evacuations on the day following its administration, not more. In either case the tendency to frequent passages in the later stages of the attack is favorably influenced by the repeated administration of this drug during the first week. If the case does not come under observation until after the tenth day, one only, or at most two doses of calomel are given. No further doses of it are, however, given during the course of the attack unless constipation occur. In this event, if the evidences of extensive or deep implication of the intestinal wall, such as abdominal pain, tenderness or marked tympany are absent, calomel in $\frac{7}{8}$ grain (0.5 gramme) doses is given at intervals of three or four days. If there

is reason to suspect serious intestinal lesions, the lower bowel may be more safely emptied of its contents every third or fourth day, by enemata of moderate size (8 to 10 fluid-ounces.) It is necessary to bear in mind that the gravest lesions of the gut, leading even to hemorrhage and perforation, have occasionally been observed in cases characterized, not only by constipation, but also by an entire absence of pain or tenderness, and very moderate tympany. The danger of salivation from calomel in these doses in enteric fever appears to be slight. In only one case in sixteen were the mercurial fetor and slight swelling of the gums observed.

Excessive diarrhoea has been controlled by the use of opium, either in suppositories, containing 1 grain (0.06 gramme), or by the mouth in quarter grain (0.016 gramme) doses, often associated with bismuth and given *pro re nata*. It is an invariable rule that the patient be kept in the horizontal position, and to the use of the bed-pan and urinal, from the time of the recognition of the disease until defervescence is completed. He is, however, turned upon his side from time to time, and made to maintain that position for twenty or thirty minutes, if necessary, being supported by the nurse.

From the beginning of the attack, the following mixture is readily administered in doses of one, two, or even three drops in a sherry-glassful of ice-water after food, every two or three hours during the day and night:

R.	Tinct. iodinii,	f3 ij.	8		00 c. c.
	Acid. carbolic liq.	f3 j.	4		00 c. c.

M.

Unless some unusual circumstances occur to render a change necessary, this medicine is not suspended until the attack draws to a close. It is well borne by the stomach, and excites no repugnance on the part of patients. In one case only has it been necessary to omit the carbolic acid on account of the disgust assumed by its odor.

Partly for the sake of its favorable influence upon the skin, and for the sake of cleanliness, partly because of its favorable though slight influence upon the temperature, the patient is to be sponged twice a day with equal parts of aromatic vinegar or alcohol, and cold water. If it is more grateful to him, this sponging may be done with tepid water, the evaporation of an extensive film of water not below the temperature of his body probably being not wholly without a refrigerating tendency.

When the evening axillary temperature reaches 104° F. (40° C.), quinine in massive doses, 24 to 30 grains (1.66 to 2.00 grammes), is given upon a falling temperature. I usually direct 8 to 10 grains to be given in solution at 5, at 5:30, and at 6 a. m., the following morning. Administered thus at the decline of the temperature in its diurnal revolution, these large doses of quinine depress it from 2.5° to 3.5° F. (1.4° to 1.8° C.). After the lapse of forty-eight to seventy-two hours, if necessary, the dose may be repeated. If these doses be rejected by the stomach—an unusual circumstance—half the quantity of quinine may be administered hypodermically. For this purpose a citric acid solution is to be preferred. Since the adoption of the plan of treatment un-

der consideration, I have not encountered cases attended with such hyperpyrexia as has rendered attempts to control it by cold baths necessary or even advisable.

The minor nervous symptoms are best held in check by skilful nursing. For the relief of the headache of the first ten days absolute quietude, a dim light, etc., are often sufficient; occasionally the bromides alone or in combination with chloral are required. Later in the course of the disease chloral is unsafe. From the end of the first week the patient cannot be left unattended even for a few minutes, without risk. Persons in whom delirium was only occasional and transient, have in many instances destroyed themselves during the momentary absence of the nurse.

Alcohol is not often indicated prior to the beginning of the third week. It may, however, by reason of the habits of certain patients, be necessary throughout the attack. Although forming no essential part of the treatment, it is commonly administered in varying though usually small amounts towards the close of the sickness. Some patients do well without taking it at all. It is of course administered in accordance with well-understood indications upon the supervention of delirium, ataxic symptoms and the evidences of failures of the forces of the circulation. The patients are carefully watched well into convalescence, and cautioned against too soon regarding themselves as restored to health.

The dangers of the establishment of a focus of contagion are guarded against by the systematic, thorough disinfection of the stools immediately after they are voided.

The considerations which led me to adopt the plan of treatment indicated in the foregoing sketch, are:

1. A feeling of dissatisfaction regarding the expectant method of treating enteric fever. This feeling, vague at first, grew more definite and stronger with increasing clinical opportunities, and a fuller knowledge of the natural history of the disease, until it became a motive, impelling me to cast about for some different and more satisfactory plan. This feeling, has been during the past decade, a very general one in the profession in all parts of the world, as is attested by an almost endless succession of journal articles setting forth new plans of treatment, and the use of new drugs, in the management of this, the most common and most important of the acute infectious diseases of the present epoch in medical history. Most of the plans thus suggested have led to disappointment when tested by the fuller observations of the profession; many of them have failed to attract general attention, and some few are still *sub judice*. Their number and diversity bear witness to a wide-spread distrust of the once well-established expectant treatment. This distrust is, however, based upon something more tangible than a mere feeling of dissatisfaction. The statistics of all observers whose cases have been sufficiently numerous to be trustworthy, show enteric fever to be, when treated by the expectant plan, a disease of high death-rate.

The percentage of fatal cases rarely falls below 15 per cent., and often exceeds 25 per cent., according to the hospital records of this country, Great Britain, and Continental Europe. Jaccoud,

with a collection of 60,000 cases, observed a mortality of 20 per cent.; Murchison, in 27,051 cases, 17.45 per cent.; Liebermeister, in 1718 cases, at Basle, under an expectant plan, records 27.3 per cent. of deaths. But turning from broad generalizations to personal experience, who is there here that many times, elated by the happy issue of mild or average cases treated by the expectant plan, has not realized the sense of utter powerlessness attending it when he has stood face to face with cases in which to *do* rather than to *wait* has been necessary to save life.

2. Enteric fever is the very type of the general diseases, of affections *totius substantiæ*. The tissues are universally implicated in the morbid processes; no function of the body wholly escapes perturbation. For this reason plans of treatment suggested by the prominence of certain groups of symptoms, or by the known lesions of particular organs, even though of undoubted benefit as far as they go, are in theory unsatisfactory because they are directed in effect against conspicuous manifestations of the cause of the sickness, rather than against the cause itself.

Whilst in actual practice the treatment by turpentine, by alcohol, by opium with lead, or the silver nitrate, or by agents capable of controlling the febrile movement, as quinine, digitalis, salicin and the salicylates, even the cold-water treatment itself, although at times and in the hands of certain clinicians showing favorable results—all these have failed of general acceptance on the part of the profession.

3. The general character of the disease, the specific nature of its cause, the unsatisfactory results alike of an expectant and of a symptomatic plan of treatment, or rather of the two combined, have united to render the idea of a specific treatment, a true cure for enteric fever, a most attractive one, to stimulate thoughtful observers to renew again and again the disappointing search for it. To this idea may be traced the treatment by the mineral acids, by chlorine-water, by carbolic acid, by quinine alone, by quinine and digitalis, by iodine, by the potassium iodide, by calomel.

4. Not only is the conception of a specific treatment for specific diseases a most attractive one, and the attainment of such a treatment for enteric fever brought within the bounds of a reasonable hope by the analogy of syphilis and the malarial diseases, but the search after it with due caution and judgment has also the warrant of the very highest medical authority.

Passing by some earlier names, I refer to Da Costa, who has said: "It would be as illogical as absurd to suppose that we shall never possess the coveted means really to cure the continued fevers. Doubtless to the physicians of the time of Charles V. the radical and specific treatment of the malarial fevers appeared as hopeless and remote as the radical and specific treatment of the continued fevers appears to the scientific inquirer of our day."

I refer also to Liebermeister, who treating about 800 cases, part with calomel, part with iodine, had with the former drug a mortality of only 11.7 per cent. with the latter of 14.6 per cent. against 18.3 per cent. for cases treated without those remedies, but in other respects upon a similar plan.

Bartholow has also spoken in favorable terms of the treatment by iodine in combination with carbolic acid.

The treatment adopted is thus seen to consist of the use of the two remedies that are proved to exert a favorable influence upon the disease, iodine and calomel, with the addition of carbolic acid in minute amounts. I am aware that no positive conclusions as to the efficacy of particular plans of treatment can be deduced from a limited series of cases. I am also aware that few acute diseases show greater variations in intensity and in the percentage of mortality at different periods, and under different circumstances, than enteric fever. Nevertheless I have ventured to occupy your attention with this subject to-night, because the results of the treatment encourage me to hope that its discussion in this way will lead to its trial on a more extended scale. That it amounts to a specific treatment in the narrow sense, is not affirmed. It is tentative, provisional, but it is nevertheless to be regarded as a contribution to the subject of the specific treatment of enteric fever.

The total number of cases treated by this plan is sixteen; all recovered, one being now in the second week of convalescence.

Of these, eight were severe, the temperature reaching or exceeding 104° F. (40° C.).

Of these eight severe cases, one was characterized by uncontrollable vomiting in the third week. The patient retained no food taken by the mouth for five consecutive days.

One case was very irregular in its course, and was complicated by an obscure abdominal abscess which discharged by the bowel. The temperature in this case on two occasions attained 105° F. (40.5° C.). This case presented the characteristic eruption of enteric fever.

A third case was prolonged by a severe relapse.

Of the eight cases in which the observed temperature did not at any time attain 104° F. (40° C.), and which were therefore looked upon as medium or mild cases one was complicated by crural phlebitis, and another by the occurrence of intestinal hemorrhage.

The average duration of the eight severe cases was about 31 days; that of the eight mild and medium cases was about 25 days.

Of the whole number ten were treated in hospital, six in private practice. All from the time of their coming under observation were under my personal care.

In two cases the special plan of treatment was abandoned about the beginning of the third week, on account of the supervention of unusual symptoms of great gravity. These related respectively to gastric irritability and an obscure abdominal abscess.

These sixteen cases are unfortunately not a consecutive series. During the year in which I have had the opportunity of observing them, two other cases of enteric fever have occurred in my hospital practice, in which this plan of treatment was not employed. One was that of a man suffering from rheumatism, who, after a stay of several weeks in the wards, and in a bed near that occupied by a patient very ill of enteric fever, was observed to be febrile, and to have the typhoid eruption. This person, previously greatly re-

duced, was not regarded as a suitable subject for a special treatment, the efficacy of which was not yet established in my mind. The other was a man who, with an obscure history of a sickness of many weeks, and a very irregular temperature, developed the typhoid eruption, and within forty-eight hours had general peritonitis. These two fatal cases have however no bearing upon the result of the treatment.

In private practice several cases of mild continued fever of long duration were treated upon this plan during the past winter. I believe them to have been anomalous cases of enteric fever, but as the rose-spots of that disease were absent, and their departure from the typical disease was wide, I have not included them in the above collection of cases treated. They all recovered.

The result of this plan of treatment has not only been satisfactory in respect of the recovery of all the cases treated, an accidental circumstance not liable to mislead persons familiar with the disease, but it has also been satisfactory in respect of the general course of the attack, and the appearance of the patient. These were in the main, despite the severe type of the disease in several of the cases and despite the occurrence of grave complications, favorable. I make this statement with due regard to the personal equation, and with no willingness to permit the observed fact to differ from the actual fact; for I desire any who may make trial of this plan to be more favorably impressed with the results of it, than they have been impressed with my account of it.

After the reading of the preceding paper:—

Dr. George Hamilton spoke of the great importance of preventing hypostatic congestion by changing the position of the patient from time to time. This was one feature of the plan of treatment recommended some time ago by Dr. Wm. Pepper, in typhoid fever, by which he obtained the unequalled result of 98 per cent. of recoveries. He was not, however, at the time, able to recall in detail the method of treatment.

Dr. J. T. Eskridge stated that the treatment to which Dr. Hamilton referred consisted in the administration of nitrate of silver, and was that which had been introduced by the late Dr. J. K. Mitchell some years ago.

Dr. Roberts Bartholow said that the plan of treatment of typhoid, advocated in the very interesting and able paper just read, is, as all present probably know, in part, the so-called "specific" method. The administration of calomel in full purgative doses during the first week serves a double purpose: it has an effect on the range of temperature, and it acts on the typhoid germs present and multiplying in the intestinal canal. The use of iodine—usually Lugol's solution—throughout the disease, is also one mode of the specific treatment. By the use of this medicine, it is attempted to prevent the multiplication of germs in the intestine, to check fermentation, and to maintain an antiseptic action in the blood.

Although the existence of typhoid germs has not been proved, it must be regarded as possible. Klein, a few years ago, announced the discovery of the specific organism of typhoid in the affected intestinal glands, but Creighton of Cambridge showed that the supposed germs were produced by the mode of preparation. This *fiasco* threw

great discredit on the whole question of germs. Nevertheless, the course of treatment directed against supposed germs—the antiseptic method—has had a most favorable influence on the progress and mortality from typhoid. Whilst the specific plan has been advocated in Germany, the Montpellier school have brought forward carbolic acid as the remedy, and the success which has attended the use of this remedy has been really remarkable. Quite a different complexion has been put on the statistics of mortality since they began the use of carbolic acid. It is probable that the combination of carbolic acid and iodine gives better results than the use of either singly. According to my observation, this method of treatment diminishes the diarrhoea, lowers the fever, and renders the disease much less violent, consequently lessening the mortality. Dr. Wilson has, therefore, rendered us a real service by drawing attention anew to this plan of medication, and especially by supporting his position with valuable cases and statistics. Besides this use of medicines, Dr. Wilson's treatment contains many valuable suggestions and practical methods, which, no doubt, contribute materially to his success.

Dr. J. M. Da Costa spoke of the purgative

treatment in enteric fever, as that which had been tried in the French Hospitals and for a time sanctioned by Louis. As regards calomel it was partly by its purgative action that it was supposed to be beneficial. In his hands the calomel treatment had not yielded favorable results. He had found carbolic acid useful in controlling diarrhoea and in lowering the temperature. He had also employed thymol in one-half to one grain doses. He suggested the use of this remedy in the place of carbolic acid, as more acceptable to the stomach.

Dr. Wilson, in reply to the question of Dr. Hamilton, said that he considered it necessary to frequently change the position of the patient to prevent pulmonary hypostasis. He had intended to emphasize this point in his paper. He called attention to the fact that carbolic acid and like drugs probably exert a favorable influence upon the course of enteric fever by their power to stay the rapid decomposition of the intestinal contents, which, for lack of the antiseptic influence of the intestinal juices, the bile, etc., all of which are changed, is a secondary cause of irritation, diarrhoea and tympany. Calomel also, he thought, probably exerted an indirect beneficial influence in the same direction.

EDITORIAL DEPARTMENT.

PERISCOPE.

Physical Exploration of the Lungs by Auscultation and Percussion.

We should recognize the fact that the signs obtained by means of auscultation and percussion are not directly diagnostic of peculiar diseases, but that they represent abnormal physical conditions which are common to a greater or less number of different diseases.

To establish, says Prof. Austin Flint, *Medical News*, January 6, 1883, physical diagnosis purely on the basis of principles of physics, is to build upon a sandy foundation; he would explain by physics simply the connection existing between morbid physical conditions and their representative signs. Many of the most important signs may be studied in healthy and diseased lungs removed from the body.

We should recognize individual physical signs as such only when their constant connection with distinct abnormal physical conditions has been established; by so doing, we would have a security against an undue multiplication of signs by individualizing sounds which may be variations of established signs.

As far as may be, the differential characters of different signs should be distinct, clear, and simple.

Intensity, pitch, and quality are the points on which the distinctive characters of the sounds obtained by auscultation should be based.

The duration of the sound, the rhythmical succession of respiratory and expiratory sounds, and the apparent distance from or nearness to the ear of the listener, are all minor points not to be overlooked.

The nomenclature should be clearly and correctly expressed; it should also be uniform, "consonating." "full," "empty," "indeterminate," "wooden resonance," "band-box resonance," are all objectionable, but especially so in the designation of signs after those who have described them, as Williams, Skoda, Gerhardt, Buriner, and Wint-rick.

"When it is considered that all the knowledge furnished by percussion, which is available in the physical diagnosis of pulmonary diseases, may be comprised in four signs, one is led to exclaim, What is to hinder the possession of this knowledge to the fullest extent of every practitioner! There is no hindrance beyond unanimity in the recognition of the existence of these signs, and that practical acquaintance with their differential characters, which requires but a very moderate amount of time and attention. Arranged in pairs, the four signs are: 1. Flatness and dullness. 2. Tympanitic and vesiculo-tympanitic resonance."

Flatness and dullness are simply degrees of the same morbid physical conditions. Flatness is absence of sound; there are, of course, no degrees or varieties of flatness.

In dullness, the resonance is more or less diminished; "in dullness the pitch of the sound is invariably higher than that of the normal reson-

ance of the person examined;" this is important in recognizing slight degrees of dullness.

Tympanitic and vesiculo-tympanitic resonance relates to quality of sound.

There is absence of the vesicular quality of normal resonance, in tympanitic resonance; *a resonance in which the vesicular quality is absent is always tympanitic.*

It does not follow that a resonance, in order to be tympanitic, must be louder than the normal resonance; but a tympanitic resonance is invariably higher in pitch than the normal resonance; the contrary is, however, stated by many writers. Other things being equal, the pitch is lowered, the larger the free space containing air; a practical point of importance pertaining to tympanitic resonance, is its ready conduction for a greater or less distance beyond the limits of the space whence it comes.

A practical point in developing the cracked-metal resonance is, that the intonations may very often be perceived by the ear close to the open mouth of the patient, when otherwise they escape observation.

Vesiculo-tympanitic resonance is distinguished from the normal resonance by the presence of more or less of the tympanitic sound, by greater intensity, and by a higher pitch. It is the sign of pulmonary emphysema, "there is a liability to error in the non-recognition of this sign in certain cases of pulmonary emphysema; and consequently to an unfortunate mistake in diagnosis. As a rule, in emphysema, the upper lobes of both lungs are affected, and the lobe of the left in a greater degree than that of the right lung. Now, under these circumstances, the upper lobe in both lungs yields a vesiculo-tympanitic resonance, but this sign is more marked on the left than on the right side, the difference corresponding to the difference in the degree of emphysema. The error is in regarding the lesser degree of resonance on the right, compared with the greater degree of increased resonance on the left side, as dullness which, taken in connection with the symptoms, would point to a phthisical affection." This mistake is not infrequent.

Pyæmia from Syphilitic Bone Disease.

From the *Medical Times and Gazette*, December 30, 1882, we learn that before the Pathological Society of London, Mr. Victor Horsley related the case of a man who came under his care with eleven large abscesses in the cellular tissue, secondary, he believed, to necrosis of his frontal bones. At the post-mortem examination there was found to be acute necrosis of the malar, frontal, nasal, and inferior turbinated bones; the frontal bone was also excessively sclerosed. The mucous membrane of the nose and pharynx showed acute hyperæmia and recent ulceration. The lungs were somewhat cirrhotic at the apices. The brain contained an excess of cerebro-spinal fluid; the arachnoid and pia mater at the base were opaque and milky; the left lobe of the cerebellum was congenitally deficient, the flocculus being absent. The ventricular surfaces of each cusp of the aortic valves were ulcerated and covered with a layer of fibrin, which he regarded as pyæmic. The interesting point was that there

was no visceral lesion of pyæmia, except the heart affection. He also showed some micro-organisms found in an abscess in another case of pyæmia. In regard to the presence of these organisms, he recollected a case of pyæmia in which they were found, and as the patient improved they diminished in number in the newly-formed abscesses, until before his recovery they had quite disappeared.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—Medical journalism is as popular a field as ever. The *Medical Age*, Vol. I., No. 1, comes to us from Detroit. It is edited by Dr. J. J. Mulheron, who is no novice to the pen, and published by George S. Davis, as a semi-monthly.

—*Godey's Lady's Book* for February contains the usual amount of matter interesting to the domestic circle.

—Dr. Wade Minor Logan, of Cincinnati, has reprinted his articles on the "Curability of Consumption" in a pamphlet of 20 pages, with illustrations. Price 10 cents. His views merit consideration.

—The *New York Medical Journal*, formerly a monthly, has become a weekly. We are informed that to take its place another monthly is projected in New York. There is a definite field for a monthly medical journal, and in some respects a better one than for a weekly. The monthly is the proper medium for long, serious, studied articles, and we hope that New York will appreciate this.

—The *New York Medical Record* is emulating the blanket sheet dailies, and has extended its superficial area. It is determined to give more square inches of printed paper than its competitors.

BOOK NOTICES.

American Hero-Myths. A Study in the Native Religions of the Western Continent. By Daniel G. Brinton, M. D. etc., H. C. Watts & Co., Philadelphia, cloth 8vo., pp. 251. Price \$1.75.

The Maya Chronicles. Edited by Daniel G. Brinton, M. D., etc., Philadelphia. Published by the editor. 1 vol., 8vo., pp. 278. Price \$3.00.

Some wise man has given the advice that every professional worker should also cultivate some branch of study outside of his profession, to which he can turn for change of mental activity. This has evidently been the theory followed by the

senior editor of this journal, as the two handsome volumes named at the head of this notice abundantly testify. They are contributions to a field of learning in which he has already become pretty well known, to wit, the history, myths, and languages of the aboriginal inhabitants of America.

The "Hero-Myths" deals with a series of traditions which appear to have been found over both North and South America, all very much alike, though told by tribes wholly apart in language, in culture, and in location. The hero of the myth is the venerable man to whom the tribe attributes its political organization, such as it was, its religious doctrines, and its knowledge of the arts of life. He was generally supposed to have come from the east, and at the conclusion of his mission returned there, not to die, but to remain for a time, and was expected back again some day. What is curious is that he was very often spoken of as a white man and bearded, and this by tribes who had no knowledge whatever of the existence of a white race of men. Dr. Brinton explains these singular facts by an ingenious hypothesis, too extended to give here.

The "Maya Chronicles" is a publication entirely for specialists. A member of the profession, the late Dr. C. H. Berendt, obtained, while traveling in Yucatan, copies of some ancient manuscripts in the language of the natives of that country, the Mayas. They contained, among other records, five brief chronicles of the nation, carrying its history back about to the beginning of the Christian era. On the death of Dr. Berendt, these manuscripts were secured by Dr. Brinton, who studied the Maya language sufficiently to make translations of these chronicles; and he has published them in this volume in the original tongue, with his rendering into English, and backed by an introduction and an ample apparatus of notes, philological and historical. Any one touched with the mania of the antiquary, will find here solid food enough to give him a full meal.

M.

A Text-Book of the Diseases of the Ear and Adjacent Organs. By Dr. Adam Politzer. Translated and edited by Dr. James P. Cassells. Phila., Henry C. Lea's Son & Co., 1883. Cloth 8vo., pp. 800.

The name of Dr. Politzer is indissolubly associated with the progress of aural surgery during this generation. The treatise which he has written on this branch has long been a standard in Germany; and this translation of it, with the author's approbation, and by one of the most eminent aurists of Great Britain, will certainly take

rank as a standard work of reference for years to come.

The volume begins with a complete exposition of the anatomy of the ear and the physiology of audition. Then follows a discussion of the diseases of the several portions of the organ, the middle ear, the mastoid process, the internal ear, etc. Injuries of the organ, and the relations of ear-disease to life assurance, are also treated of. The book closes with chapters on malformations of the ear, deaf-mutism, hearing instruments for the deaf, and a satisfactory index.

The text is elucidated by more than two hundred and fifty illustrations, and the manufacture of the book is generally quite satisfactory, though some of the cuts are not quite all that one could desire.

Early Aid in Injuries and Accidents. By Friedrich Esmarch. Translated from the German by H. R. H. Princess Christian. Philadelphia, H. C. Lea's Son & Co., 1883, 8 vo. clo., pp. 117.

There is in Germany a so-called "Samaritan Society," whose members fit themselves to render aid in the accidents and emergencies of life and in sickness. It was founded, we believe, by Prof. Esmarch, and this volume contains the translation of five lectures which he delivered before it.

The first lecture gives a popular synopsis of anatomy; the second, third and fourth are on various injuries; and the fifth is on transport of the sick and wounded.

While they contain nothing which is not familiar to professional men, they present in a clear manner a great many points which it were well for all to know who are liable to be called upon to aid the injured and sick—and who is not?

Hygiene and Sanative Measures for Chronic Catarrhal Inflammation. Second edition. By Thos. F. Rumbold, M. D., St. Louis. Medical Journal Publishing Company, 1882.

As a specialist on catarrh, Dr. Rumbold ranks among the first we have in this country. The appreciation of his works is shown by the appearance of this second edition, the first having been exhausted in less than a year.

The present one has been rewritten and material additions made. The author has no specifics to recommend nor mysterious cures to report, but distinctly lays down the principle, which all scientific physicians will endorse, that the most successful treatment of chronic catarrhal affections is "through the enforcement of proper hygienic measures."

The work has a number of illustrations, and is well printed and bound.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

THE SANITARY INSPECTION OF SCHOOLS.

The fate of the future is held by the children of the present age, and it is this consideration which should be ever present with legislators and those who pursue state-craft. They have no more solemn duty than to provide every wise facility that these children be educated in sound moral principles, solid intellectual culture, and the most judicious physical surroundings.

It is a pleasure to record that the citizens of Ohio appear to appreciate this axiom of a free government.

The following amendment of one of the revised statutes (section 2135) is now before the Legislature of that State, and no doubt will be passed without difficulty. The portion in brackets is the amendment proposed:

SEC. 2135. The Board of Health may take measures and supply agents, and afford inducements and facilities, for gratuitous vaccination and disinfection, may afford medical relief to and among the poor of the corporation, as in its opinion, the protection of the public health may require; and during the prevalence of any epidemic, may provide temporary hospitals for such purposes [and the said Board is hereby required to inspect semi-annually, and oftener if in the judgment of the Board it shall be deemed necessary, the sanitary condition of all schools and school buildings, within the limits of the corporation].

All who are interested in the future of the enlightened State which has thus taken an efficient measure to provide for the physical welfare of its school children, will read the above with pleasure.

It is clearly not sufficient to leave such an important matter as the hygienic condition of schools to chance visits of competent persons, or to occasional inspection by school boards. The latter, however well intentioned, have not the special training needed.

Still more deplorable is it when through neglect of preventive measures an epidemic breaks out in a school. Every parent is interested in this question, every community should feel it as a personal matter. The sad loss of the bright faces around the family board will be a matter of lasting self-reproach to those who are indifferent to claims on their attention like these.

We confidently expect that Ohio will promptly

adopt this amendment, and we feel that by so doing it will set a noble example to many other States.

A FOOLISH EXPERIMENT.

A man in New York has gained a certain amount of notoriety by making a wager that he would eat thirty pairs of quail in thirty consecutive days, one pair each day. That nothing is to be gained to science by this experiment, whether it succeeds or not, is self-evident, and we suppose the party interested cares not, so long as he wins his wager. But a man ought not to be allowed to thus foolishly trifle with his stomach.

Were he to try how long a man could live on any one exclusive article of diet, and place himself under the care of an intelligent physician, for observation, while so experimenting, he would prove a benefactor to science. Such meaningless exhibitions are useless and disgusting.

A STATE BOARD OF HEALTH AND ITS DUTIES.

It is to be hoped that no further delay will take place in organizing a Board of Health in this State. That it has been delayed this long is a disgrace—neither more nor less—and a discredit to the Commonwealth.

The bill now before the House of Representatives is a well-matured one, and should be promptly passed.

The duties of such a Board of Health, embracing as the field of its operation the whole State, are of vast importance to the people. Their health, their lives, and consequently their prosperity and happiness, are protected and advanced by the judicious exercise of the powers of such a sanitary body.

This is conceded on all hands when it refers to the crowded areas of cities, and it is not a whit less true when it is applied to rural districts. The difference is only that in the one instance the benefit is palpable, and immediately before the eyes of thousands; in the other it is just as real, but there are fewer to note it.

A Board of Health should stand in close relation to the medical profession. In no sense should it

be a political machine, nor should it have the immediate expenditure of much money. It should be observant and advisory, and its opinions should be heeded as those of unbiased experts.

It is quite proper that it should have the general supervision of medical practitioners, and be the body which officially decides on the propriety of admitting applicants to practice. In this view the following bill now before the Legislature deserves the support of the profession:

An Act Supplementary to an "Act to Provide for the Registration of all Practitioners of Medicine and Surgery."

SEC. I. *Be it enacted, etc.*—That the duties imposed upon the Faculties of the Medical Colleges and Universities in this Commonwealth set forth in the fourth section of an "Act to Provide for the Registration of all Practitioners of Medicine and Surgery," approved June 8th, 1881, are hereby transferred to and imposed upon the Board of Health of this Commonwealth; in like manner the duties imposed upon medical practitioners set forth in the same section of said act are hereby extended to and imposed upon all persons who may desire to commence the practice of medicine or surgery; and said Board of Health being satisfied as to the genuineness of the Medical Diploma presented to them for inspection, and also being satisfied as to the qualifications of the holder of such diploma to practice medicine or surgery, shall direct their secretary to endorse the same; after which the prothonotary may register such practitioner as indicated in said act of Assembly.

SEC. II. Said Board of Health shall have the supervision of the registration of all practitioners of medicine and surgery; they shall appoint a committee in and for each county, to be composed of three or more resident practitioners, whose duty it shall be to prepare a report in such manner and as often as may be ordered by said Board of Health, giving in it the condition of the Medical Register of their county; they shall make affidavit before the prothonotary of their county that the report is correct and true, and shall forward the same to said Board of Health.

SEC. III. If any practitioner has registered or shall register the degree of Doctor of Medicine, and has set forth or shall set forth that the same has been conferred by a medical society, or by an institution which has had a doubtful or precarious existence, or by an institution whose name does not indicate that it has been or is a medical college or university, and it cannot be ascertained that lectures on Human Anatomy, Human Physiology, Materia Medica, Chemistry, the Practice of Medicine and Surgery and Obstetrics have been regularly delivered in such institution, said Board of Health shall notify such practitioner to appear before them, and to present for inspection his or her medical diploma, together with any catalogue or announcement by which information may be given concerning such institution; and the practitioner, failing to show that his or her diploma was issued by a legally-chartered medical college or univer-

sity, and obtained in a regular manner, as provided in said act of Assembly, said Board of Health shall direct the prothonotary to cancel such registration.

It is further specified that the registration of physicians, who practice without a diploma shall cease in three months from the passage of this act.

As other states are busy purging from their confines the unworthy parasites of the profession, who batten on the public and bring discredit on medicine, so we hope that Pennsylvania will no longer be a laggard in this race for advancement.

We ask all our readers in this State to help along the good cause by personal appeals to their representatives.

THE NEW CODE OF ETHICS.

Notwithstanding the fact that numerous County and State societies, as well as the American Medical Association itself, have placed the seal of disapproval upon last year's action of the New York State Medical Society in allowing its members to meet in consultation with Homeopaths; and in spite of the fact that the Homeopaths themselves have not seemed generally overjoyed by this action; yet the New York County Medical Society, at a largely-attended meeting last Monday evening, defeated, by a large majority, a motion to instruct their delegates to the State Society to vote to rescind the innovation, and by a very large majority endorsed last year's action.

This seems very much like the story of the obstinate jury, wherein *eleven* men were reported to be so *pervse* that they actually stood out against one.

We trust the American medical profession will be equally obstinate, and will at Cleveland repeat the lesson it read at St. Paul.

It is but just to note that the leaders of the profession in New York city, such men as Sayre and Flint, bitterly denounce the action of the County society.

—The scientific world and the many friends of Professor Owen will be sorry to learn that the state of his health is such as to cause great anxiety.

NOTES AND COMMENTS.

Paralysis After Fracture.

At a recent meeting of the Société de Chirurgie, M. Trelat presented a patient who was brought to his service with a fracture of the femur and of the left forearm. The usual apparatus was employed. Towards the end of May it was found that the patient was affected with complete radial paralysis of the left forearm; the callus was exuberant.

On June 1, an incision was made over the callus, and after considerable difficulty, the radial nerve was found compressed in an oleo-fibrous canal towards the superficial surface of the callus. The nerve was disengaged with the chisel and mallet, and the surface of the callus resected.

From previous experience, M. Trelat did not expect any immediate favorable result, and no movements were observed until two months later; after that, a period of two months passed before the paralysis completely disappeared.

An Improved Vaginal Douche.

The Boston *Medical and Surgical Journal* contains an article, by J. B. Gerauld, M. D., upon an improved method of the vaginal douche. Dr. Gerauld says that this practice is not extensively used outside of hospitals, and that the apparatus for its execution is too expensive for many. He deprecates the use of pillows, rubber cloths, chairs, etc., because the patient is overcome by the "manifold directions," and generally saturates herself and surroundings with water, and from this cause becomes disgusted with the treatment. There is considerable truth in the doctor's deductions, but we cannot see that he makes the matter much plainer as regards *manifold directions*. An ingenious and simple contrivance described by the doctor is no doubt very efficient, but its manifold directions seem confusing, viz.: blanket, syringe, chair, hot water, board constructed as follows: either pine or white wood, from ten to twelve inches long, ten inches wide; on under side of which two strips, two and a half by twenty-four inches, are nailed; uniting the two free ends is a short strip which hooks over round in chair, thus preventing slipping. It is not necessary to mention the other half of directions; but besides these, a skillful gymnastic movement must be performed in order to mount and start the stream. Taking everything into consideration, it seems as if a fairly interesting case of hysteria might be originated by these *manifold directions*. But the doctor's idea is good.

Early Diagnosis of Pulmonary Tuberculosis.

The *Medical News*, in an extract from *L'Union Médicale*, says: "That more value than has heretofore been believed can be attached to the presence of anomalous respiratory movements in the early diagnosis of tuberculosis of the lungs; and when the irregularity is localized in the apex of the lung, particularly on the left side, and is permanent, it permits of a positive diagnosis, seen in the absence of other signs, such as crackling or alterations in the vocal fremitus or pulmonary resonance. These respiratory anomalies, in the order of their importance, are rough and deep inspiratory murmur, feeble and jerky respiratory movements. Harsh and deep-toned inspiratory murmur is the most valuable sign, as it is the earliest which appears."

These points, which Dr. Grancher calls attention to are of undoubted value to the early diagnosis. The only point on which we would differ is the fact of the doctor laying particular stress on the localization of these anomalies in the left apex: private statistics of ours on a hundred cases of early or incipient phthisis show quite a respectable majority in which these signs were confined for a time to the right apex alone, the left only becoming tuberculous after a time.

Ether Injections vs. Transfusion.

From the *Gaz. des Hôp.* we learn that Professor Hayem recently read a paper before the Académie de Médecine, in which he related the results of his experiments, in controversion of the accuracy of Prof. Verneuil's statement that transfusion is a useless operation, which may be superseded by hypodermic injections of ether. Having bled a dog almost to the point of death, he found that the injection of ether was attended with no durable effect, while transfusion produced a "true resurrection." When a large quantity of blood was withdrawn, the dilution of what remained by the transfer of the serum derived from another dog was also attended with the same success. The stimulation by ether only produces an increase in the energy of the cardiac contractions and a notable increase in the number of the pulsations, but does not give rise to any increase of the pressure of the blood nor of the rectal temperature.

Pelletierine and Koussou.

In a recent discussion in the Soc. Médicale des Hôpitaux, M. Laboulbène, in answer to a question on the subject by M. Féréal, said that he had always found Tanret's Pelletierine successful for the expulsion of tænia, but he considered the usual

dose (grains 3 to 5) rather feeble, and generally gave 7 grains. The drug should be given in doses sufficient to induce vertigo and nervous phenomena. It was the opinion of most of the members (Dujardin-Beaumetz, Tenesson, Mesnet) that a purgative, castor oil or a black draught, should be given half an hour after the administration of the anthelmintic.

In one case where Pelletierine proved unsuccessful, a druggist took pepsin and passed the tænia in a softened mass. M. Laboulbène remarked that koussou when fresh is purgative and anthelmintic, but the active principle is a glucoside which becomes altered with time.

Pregnancy.—Cancer of Cervix.—Cæsarian Section.—Recovery.

Dr. Edis presented this case to the Obstetrical Society of London, and we take the report from the *Lancet*, December 30, 1882:

"The patient came to Middlesex Hospital in November, 1881. She had begun to suffer pain, hemorrhage, and discharge eleven months previously. She presented the signs of six months pregnancy, and there was epithelioma involving nearly the whole circumference of the cervix and the greater part of the posterior vaginal wall. Palliative treatment was adopted until February, 1882. Labor pains then came on, and the os dilated to the size of a five-shilling piece. It being judged impossible for delivery *per vias naturales* to take place, Cæsarian section was performed by Dr. Morris. The child was born in a state of suspended animation, but recovered. The mother recovered, and when seen in September the disease had made but little progress.

CORRESPONDENCE.

Hæmaturia—Diphtheria—Typhoid Fever.

ED. MED. AND SURG. REPORTER:—

I think I have made a discovery. We had during the past summer many severe cases of hæmaturia with intermittent and congestive type of fever. I found that quinia alone did not succeed well. But with the infusion of the spice-wood, benzoin odoriferum, as a drink in the place of water, as much as two or three cups full every day would soon control the hæmaturia. Since I have treated several milder cases of hæmaturia with the spice-wood tea, I am persuaded from my 9 months experience with the remedy that it is worthy of confidence in bloody urine, particularly if all complications are remedied.

I see so much written about diphtheria, sore throats and the like, and the prescriptions given—may I add one to the list that has never failed

me, if the remedy touches the ulcer or part inflamed :

R. Potass. chlor.,	ʒjss.
Argenti nitratis,	gr. x to xx.
Tr. opii,	ʒj.
Acid. carbol.,	gtt. xxv.
Aq. rosæ,	ad ʒvj.

Directions.—Gargle or touch the surface every four to six hours.

Another: In our typhoid type of fever that drags along so slowly—(after all complications removed, if any) and with just oil enough to regulate the bowels—(sometimes the discharges are small and too frequent, etc.) I consider the following a panacea, changing ingredients as required.

R. Ol olive,	
Tr. opii camph.	
Spts. ætheris nitrosi,	āā ʒ ss.
Acid carbol.,	gtt. xxv.
Aq. tamarind,	ad ʒvj.

M. Sig. 1 tablespoonful every 3 hours.

One can see a benefit in the course of 36 hours.

Louisiana.

R. M. NICHOLLS, M. D.

The Opium Habit.

EDS. MED. AND SURG. REPORTER:—

I have seen and read much of the distressing effects of the morphia habit; and I know of a case that is an unusual one to me, and I write to know if you or any of your readers have met any similar.

A young man of nervous temperament, delicate, about 35 years of age, had used from two to three drachms of sulphate of morphia per week for over two years. He quit taking it some four weeks ago—stopped it at once, without any inconvenience or the ill effects so usually experienced from its use. Had no effect upon him perceivable. Says he feels as well as ever he did in his life, and has from the day he stopped. Why does its effect vary so much in different individuals? Any light that I can procure on this subject would be gratefully received by me. W. S. MARTIN, M. D.

Kingwood, Preston county, W. Va.

NEWS AND MISCELLANY.

The National Association for the Protection of the Insane and the Prevention of Insanity.

The annual meeting of this Association was held in this city on Thursday, January 25, 1883. Dr. Joseph Parrish, of Burlington, N. J., presided, and Miss A. A. Chevaillier, of Boston, acted as secretary.

Dr. S. D. Gross delivered an address of welcome, in which he pictured in eloquent words the misery of the insane and the nobility and grandeur of the effort to prevent insanity and to protect the insane. In the State of New York alone there are upwards of 10,500 insane locked up. The great duty of those interested in this cause, in Dr. Gross' opinion, is the proper classification of the insane, and a decision as to how they should be treated in and out of the asylum, and whether with medicine and restraint. He called attention to the few recoveries recorded among the insane, and referred to the necessity of prompt attention to the subject

of restraint, numerous frightful occurrences among patients injudiciously allowed their freedom making this imperative.

Professor Traill Green, of Easton, followed Dr. Gross in a paper on the functions of a medical staff of an insane hospital. He said that the last census showed that there were 37,000 insane and 24,000 simple-minded people in the United States; but he believed these figures were far below the actual ones, and that there were 100,000 insane persons. If there were only 50,000, the matter was one which claimed attention. He condemned the present management of our insane asylums in regard to their limited medical staff. In most of the asylums there are only two physicians to 400 and even 600 patients; whereas in the Pennsylvania Hospital for the Insane, Dr. Kirkbride has had for the past five or six years one physician to every 86 patients. Why cannot the State do the same? Dr. Mary Jacoby strongly confirmed Dr. Green's views.

Dr. Gross submitted a resolution, as follows:

WHEREAS, Numerous facts have recently been brought to light tending to show that insanity in women, in many of its worst and most embarrassing forms, is caused by sexual diseases, often of a curable nature; therefore be it

Resolved, That it is the deliberate opinion of this association that there should be upon the professional staff of every insane asylum a thoroughly trained gynecologist, competent to make all necessary examinations of, and perform all operations on, women with sexual maladies.

After some discussion, the resolution was adopted.

Dr. Charles K. Mills read a paper on "The Duty of Medical Colleges toward Mental Disorders." He said:

The number of insane people in 1880 was between 89,000 and 96,000, or 1 to every 520 of the population. There is great need for larger asylums, and greater necessity for more and better persons to take charge of them. Diseases of the mind should be the subject of special study in our medical colleges. At present they are limited to one or two lectures, and they are didactic. In my opinion they should be clinical. The University of Pennsylvania and Jefferson College should have departments in their hospitals for insane patients, with whom the students can be brought into daily contact. Attendance on the lectures should be compulsory. Physicians, wherever they practice, may have them to treat; they may be called upon to sign certificates of insanity or pass upon a patient's lunacy; in short, it is a matter of the most vital import.

Dr. Joseph Parrish read a paper on "How to Protect the Insane," in which he deprecated the building of any more asylums, and advocated the placing of the insane and inebriates in cheerful homes.

Dr. Dana offered a resolution of regret at the recent death of Dr. George M. Beard.

Miss Chevaillier recommended the appointment of a temporary lunacy commission, to go to Congress and urge the creation of a permanent one.

A resolution by Miss Chevaillier, petitioning every college to have a course of clinical and didactic lectures on psychiatry was adopted.

The Society then adjourned to meet at 8 p. m.

In the meanwhile Dr. Gross entertained the members at his home.

At the evening session the Rev. R. Heber Newton, of New York, read a paper on "The Obligations of the Sane towards the Insane"; in the course of which he dwelt upon the incarceration of sane persons for family purposes.

At the conclusion of his address his remarks were challenged by Dr. C. K. Mills, Frank A. Wells, Dr. Atlee, of the State Hospital at Harrisburg, and Dr. Morton, of the Pennsylvania Hospital.

Dr. Atlee said there may be many cases where sane persons are unjustly incarcerated in asylums in New York—in fact, the papers are full of such stories; but in Pennsylvania we can take care of our institutions and ourselves.

There was an evident disposition to carry the dispute to personalities between Philadelphia and New York, and Dr. Parrish, the President, was compelled to end the matter by ordering the discussion closed.

Clark Bell, a New York lawyer, read a long paper on the "Legal Rights of the Insane," that touched on every side of this aspect of the case—the principal point urged being as careful a supervision of the superintendents as was exercised over the patients themselves.

The officers elected for the year are: President, Dr. Joseph Parrish; Secretary and Treasurer, Miss A. A. Chevaillier; Executive Committee, Dr. Parrish, Miss Chevaillier, Clark Bell, Dr. William B. Atkinson, Dr. C. K. Mills.

The Association adjourned.

Officers of the Northern Medical Association of Philadelphia for 1883.

President.—Dr. J. T. Eskridge.

Vice President.—Dr. Henry Beates, jr.

Recording Secretary.—Dr. I. G. Heilman.

Corresponding Secretary.—Dr. Ida E. Richardson.

Reporting Secretary.—Dr. Henry Beates, jr.

Treasurer.—Dr. L. Brewer Hall.

Counsellors.—Drs. Jas. B. Walker, Edward R. Stone, Robt. J. Hess, Henry W. Rihl, Daniel Longacre.

Another Cremation.

On Friday, January 26, the body of a child three years old was cremated in the Le Moyne furnace at Washington, Pa. The subject is the child of Dr. Samuel Holm, of New York, who himself was cremated in the same furnace in 1880.

Personals.

—A physician in this city was lately sued for malpractice in the treatment of warts! He made a successful defence.

—Dr. Oliver Wendell Holmes has not lost his inclination for dining out, and his hosts find the autocrat's inexhaustible table-talk as brilliant and good-humored as ever.

—A man calling himself Dr. C. L. Blood, publisher of a book called *A Century of Life, Health, and Happiness*, was recently arrested in this city on the charge of defrauding by means of false pretences.

—Dr. R. S. Sutton, whose studies in abdominal and pelvic surgery have already gained him a widespread reputation, returns from Europe in a few weeks, after passing eighteen months in the examination of foreign methods of teaching these branches.

Items.

—Dr. S. Pollak, in the St. Louis Medical Society, reports a case of sciatica promptly and permanently relieved by the hypodermic injection of ice-cold water. The needle of the syringe was buried deeply in the tissues.

—There are thirty-four or thirty-five counties in New York State that have voted against the new code, to three or four in favor of it, or of no code at all.

—Spanish physicians are not allowed to practice their profession in Lisbon, although Portuguese doctors are freely admitted in the cities of Spain. This lack of reciprocity is causing a commotion among the Dons.

—To promote the growth of the hair, Professor Ratlin, of Leipsic, recommends (says the *Pharm. Zeitung*) a mixture of 10 parts of tincture of capsicum with 50 parts of glycerine.

—An Obstetrical Society was recently formed in Washington city, Dr. S. C. Busey, President.

—Dr. Hughlings Jackson, in a recent address, says very truly that too much specialism in teaching tends to produce prigs rather than practitioners.

—The *Quarterly Journal of Inebriety* for January, 1883, says: "A man who becomes an inebriate after forty years of age, is always the victim of some profound disturbance of the nerve centres. Some condition of disease or exhaustion is present, that has broken up the normal integrity of the brain centres, and demands alcohol simply because it brings relief to this state of irritation."

—At the close of Dr. Morell Mackenzie's lecture at the Bellevue Medical College, New York, one of the students from "out West" remarked to his neighbor, "That feller talks our language very well for a foreigner."

QUERIES AND REPLIES.

Junior, W. Va. Write to the Surgeon General of the Marine Hospital service, Washington, D. C., for the information you desire.

MARRIAGES.

PERCY—HARVEY.—On Wednesday, January 24, at Calvary Church, by the Right Rev. Horatio Potter, D. D., Bishop of New York, assisted by the Rev. H. Y. Satterlee, D. D., Professor Samuel R. Percy, M. D., and Miss L. Jennie Harvey.

SEYMOUR—MINTURN.—At Shoreham, Vermont, January 23, by the Rev. J. Isham Bliss, William Wotkyns Seymour, M. D., of Troy, N. Y., and Frances, daughter of the late Lloyd Minturn.

DEATH.

BEARD.—At the Grand Hotel, New York city, January 23, Dr. George M. Beard, aged 43 years.

No preparation of COD-LIVER OIL equals, in elegance and efficiency,

BAKER'S
EMULSION

50 per cent. Oil, with Hypophosphites of Lime and Soda.

NEW (1881) CROP of Pure Cod-Liver Oil,
now arriving via Thronthjem, Norway, per
steamer.

DR. JOS. LEIDY, Professor of Anatomy, University of
Penna., says: "Gentlemen: It affords me pleasure to have
the opportunity of recommending your Cod-Liver Oil to the
medical profession. I feel satisfied that a purer and more
efficacious article cannot be obtained in the market."

DR. RICHARD O. COWLING, Louisville, says: "We em-
ploy BAKER'S COD-LIVER OIL in preference to all others.
The Pure Oil is palatable and digestible, and the emul-
sion is well-nigh delightful."

ABSOLUTE PURITY AND FRESHNESS GUARANTEED.

AGENTS FOR

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

*A chalybeate that has all the virtues and none of the defects of all the
present official preparations of iron.*

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for
which all the above claims have been verified, both in the laboratory and by the clinical experience of many of
the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and
being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of
the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting
from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's
Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds
containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be
claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added
to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black in-
stantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts.,

PHILADELPHIA.

We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instru-
ments in the world. They range in price from \$15 to \$30, according to the number of currents. 1377-1351

ALCOHOL, ITS USE AND EFFECTS AS A BEVERAGE AND MEDICINE.

BY FRED. HORNER, M. D.,
Of Virginia.

First. Alcohol is defined in pharmacy to be rectified spirit of the specific gravity 0.835, containing 13 or 14 per cent. of water, and is obtained by the distillation of a fermented, saccharine, or vinous liquid, and is expressed by the chemical formula $C_4H_6O_2$ produced by the breaking up of an equivalent of grape sugar, $C_{24}H_{28}O_2$. Alcohol does not exist in plants. It was extracted from fermented liquors first by the Arabians, and may be divided into three classes, viz.: Ardent spirits, wines, and malt liquors. Alcohol is a colorless, limpid liquid, and of a pungent, aromatic, and agreeable taste and odor. It is volatile, and boils at the temperature of 176° F., producing a high degree of cold during evaporation. It retains its fluidity under every degree of cold to which it has ever been exposed. It is highly inflammable, and burns with a lambent, bluish flame, unattended with the least degree of smoke. The sole products of the combustion are water and CO_2 ; when transmitted through a red-hot tube of porcelain CH_3 is produced, and a trace of charcoal. It unites with water in every proportion, with diminution of volume and increase of temperature; the two together, when redistilled, and with half its weight of quick-lime, making pure or absolute alcohol. It dissolves soda, ammonia, and the vegetable alkalies and resins, such as camphor, manna, the balsams and essential oils, is largely used in the

manufacture of tinctures of which the United States Dispensatory recognizes as officinal nearly 300, not including the ethers and chloroform, and forms definite compounds with the chlorides of calcium and zinc. Its component parts are, carbon 52.17, hydrogen 13.04, oxygen 34.79. It exists ready formed in wine and spirituous liquors, and may be collected without heat. Mr. Brande, in a table, has proved that brandy, rum, gin, and whisky contain 40 to 50 per cent. of alcohol; port, sherry, and Madeira wines, 19 to 25 per cent; claret, champagne, and gooseberry wines, from 12 to 17; and cider, ale, and porter, from 4 to 10. Alcohol is simply combined with water in all spirits, whereas in wine it is combined with mucilaginous, saccharine, and other vegetable principles which tend to diminish the activity of the alcohol upon the system—a fact explanatory that while brandy, contains but little more than twice as much alcohol as good port wine, it has an intoxicating power considerably more than double. Ardent spirits, as already stated, are obtained by the distillation of vinous liquids, e. g., that from the fermented juice of the grape is brandy, that from molasses is rum, that from an infusion of grain is whisky, from rice arrack, from the peach and apple is another form of brandy, whilst gins, Hollands, Scotch and Irish whisky are corn spirit flavored; the volatile oil contained in all is termed by the chemist fusil oil. The essential oils are present in small quantity, either generated during fermentation or purposely added by the manufacturer, with adulterations of strychnine, hops, etc.

The toxicologist defines alcohol to be an acro-narcotic poison. In small quantities it causes

mere excitement. In large doses it produces delirium, confusion of intellect, nausea and vomiting, and even coma, apoplexy and death. When taken in excess, it often proves instantly fatal, or by occasioning or aggravating other diseases, may be attended by the same result. Tanner, "Memoranda of Poisons," mentions the case of a man who drank two bottles of port wine, containing eleven ounces of alcohol, in less than two hours. He died from congestion of the brain and lungs. Two wine-glasses of brandy proved fatal to a boy seven years of age in thirty minutes. The writer knew of a naval officer who drank a single bottle of wine while standing on his head, to win a wager, and died suddenly with symptoms of apoplexy; and of another example of a sailor, his patient, on board the U. S. steamship Jamestown, who drank freely from a bottle of alcohol used for lamps, and died from congestion of the lungs. In connection with the subject of the toxic effects of alcohol, it may be here added that the habitual use of alcoholic stimuli will cause diseases of the viscera, and various cerebral and nervous disorders, and the symptoms of poisoning thus induced may be mistaken for those of epilepsy or apoplexy. The morbid appearances, are inflammation and softening of the mucous membrane of the stomach with an odor of alcohol, and congestion of the cerebral vessels, with sanguineous and serous extravasation in the brain or lungs. The blood is less coagulable, than is natural, owing to a deficiency of fibrine, the principle which gives strength to the muscles. The blood is also liquid and fermentable, and has an excess of temperature. Memory, the faculty of the soul which enables man to recall and reproduce sensations and ideas, according to Dr. Winslow, in his volume "On the Brain and Mind," is either impaired or lost, and finally the morbid conditions end in insanity.

Secondly. *Its Use and Effects as a Beverage.* With the majority of men the appetite for alcoholic stimulants is acquired, though in a minority of examples the appetite is hereditary. The social habits of mankind at present in high and low life tend to encourage their use, owing perhaps to the excessive waste of brain, nerve and life forces now expended in the varied pursuits, intellectual and mechanical, which occupy the attention of mankind, to the exclusion of comfort, sleep and needful diet—and thereby violating the common rules of practical hygiene. On ship board, in cities, and in every clime, intoxicants have come into universal use. The Anglo-Saxon has by statute made beer drinking a legalized fact, the

Latin races drink wine, and the Anglo-American whiskey, all ignoring the solemn warning and Scriptural rule, "Give strong drink to him who is ready to perish." The first record we have of the use and effects of wine drinking in excess is recorded in the Bible in the history of Noah. "And Noah began to be a husbandman, and he planted a vineyard, and he drank of the wine and was drunken." The love for alcoholic stimulants is not natural to the normal man, as already affirmed; the palate rather rejects them, excepting in the case of the drunkard's offspring, in whom the appetite is innate and transmitted. In proof of this assertion, an example is furnished by the records of the Tombs Prison in the city of New York, of a youth fifteen years of age, who was arrested for drunkenness; but he was not drunk, nor had he been drinking. He had never been able to walk without staggering. His speech was that of a person intoxicated, and when excited he would mutter and reel. He had been born a natural drunkard, and had always acted like one. The evils physical and moral growing out of the use of alcoholic stimulants as a beverage throughout the civilized world, as well as in heathen lands, where the savage has been taught to drink the well named fire-water of the so-called Christian races, cannot be described. The child at the mother's breast is made to acquire a taste for stimulants by a vicious midwife—the physician, oblivious of the responsibility to protect his patient from temptation, prescribes them often without restriction as to time and quantity. And the operative classes in this country look forward to the harvest and holiday seasons as occasions for self-indulgence, even to a condition of inebriety. It can be readily proved that such is the nature of alcohol and such the nature of man, that he cannot continue to use them as an ordinary beverage without in many cases forming intemperate habits leading to drunkenness; and the assertion can be sustained by numerous examples, that the common and ordinary use of ardent spirits in American homes, towns and cities, has already peopled them with drunkards. The quantity consumed annually is well nigh incredible. The tax upon intoxicating liquors is \$70,000,000—the interest paid in one year, according to the statement of U. S. Senator Blair, for alcohol, would relieve the American nation of all taxation for the support of public schools. Philadelphia has 4,160 drinking saloons, covering the space of five acres of ground, and spends on the purchase of ardent spirits \$30,000,000—Chicago \$40,000,000, and New York \$60,000,000. In the

latter city 65,000 arrests for intoxication were made in a single year, and 80,000 were committed to public charities. In the United States 400,000 more people are engaged in the liquor traffic than in preaching the Gospel. In England, by the use and effects of alcohol, 100,000 individuals are annually sent to prison, 150,000 die drunkards, and 200,000 women and children are reduced to destitution; while in this country only \$12,000,000 are expended for the support of the Gospel, \$90,000,000 is required to keep up jails, penitentiaries, hospitals for the insane and for inebriates, and to pay the fees of lawyers and the criminal courts. In Great Britain the drink bill amounts to £108,000,000, with an annual loss to the nation for value of food destroyed, waste of capital, destruction of property on sea and land, cost of police and public charges, by pauperism, vice and insanity, traceable to drink, footing up the enormous sum of 216,000,000 pounds sterling. Villermé, a French savant, declares that "the use of wine with its ultimate effects is the greatest curse to the laboring classes of France. At the tavern they contract debts. Hatters, tailors, printers, marble cutters, and ship carpenters in that country, are the greatest sufferers." M. Fleury "Lectures concours d'Hygiene," alluding to the vices traceable in France to the use of ardent spirits, affirms that workmen at the cabarets learn to revolt against social inequalities, and there begin to dream of communism. The reports of asylums in Great Britain and in the United States disclose the fact that three-fifths of the cases which come under the notice of inspectors of such institutions were caused by the use of alcoholic stimulants. Out of the jail population in Canada of six thousand convicts, not less than five thousand owed their condition to the use of such intoxicants. While the above facts are well known, it is to be deplored that the legislation of our national Congress and the State Legislatures, and even the judiciary, encourage by statute law the liquor traffic, the support of barkeepers and of revenue agents, worse than the locusts of Egypt.

Third. *The Use and Effects of Alcohol as a Medicine.* Alcohol is used as a vehicle of medicines, or for convenient administration. In small quantities it is valuable as a cardiac and brain stimulant, and in medical practice the use of either wine or some form of ardent spirits is recommended for dyspepsia, where articles difficult of digestion have been eaten, and gastrodynia results—for diseases of an adynamic character, such as typhus and typhoid fever, diphtheria, phthisis

pulmonalis, and puerperal septicæmia. During the progress of these affections, often a marked benefit may be derived by a prompt and judicious application of vinous or alcoholic stimuli—the former to be preferred, especially in long protracted fevers, in which it is important not to hurry too much the organic actions. Whenever there are signs of great prostration, with feeble action of the heart and pulse, and a comatose condition, along with a dry red tongue and hot skin, or septic or uremic poisoning of the blood has occurred, the life of the patient may be saved by the administration of brandy or milk-punch. They act as stimulants and antiseptics. Under such circumstances, rubbing the limbs or body with spirit, as whiskey, will tend to rouse the vital powers, and avert the tendency also to death by asthenia. Alcohol in some form is especially demanded when hemorrhage occurs after parturition or from a dangerous wound or nervous shock by accidents. Captain DeLong, the gallant though ill-fated Arctic explorer, in the last items of his diary, states that alcohol in small quantities appeared to appease the intolerable craving of the stomach for food, during the period he and his noble companions were dying by inches from starvation and cold.

According to the principles of sound physiology, as well as of pathology, the practice of the free administration of alcoholic stimulants for the cure of acute inflammation of the lungs, rheumatism, etc., recommended by Robert Bentley Todd, M. D., in his clinical lectures on certain acute diseases, is not generally accepted by the profession in England or in this country. Within the past decade, there have been ardent advocates for the whiskey cure of phthisis pulmonalis and pneumonia. The effect of the remedy does doubtless retard the destructive processes induced by tubercles and subsequent disintegration and ulceration, though the suggestion has contributed to add to the scores of dipsomaniacs and inebriates. It may be asserted that alcohol exerts a pernicious influence in many instances upon the heart and arteries. The heart's action is not increased under its influence, but positive alterations in the structure of the blood vessels take place. In some examples, we find the movements of the heart permanently quickened, and the blood is therefore driven more forcibly to the brain, while the coats of the arteries, having lost their elasticity by thickening, thinning, or ulceration of their substance, are more readily ruptured by this forcible current, and hence the tendency to hemorrhage in the brain is vastly increased. In some constitutions,

speedy impairment of the cerebral functions and apoplexy occur under such circumstances. The toxicant effect of alcohol is most clearly exhibited in cases of delirium tremens and mania-a-potu. Though we have no antidote to so subtle a poison, an effort can be made to restore the secretions, and by warding off dangerous complications, may thus prove to be remedial, and contribute to the elimination of the poison from the system. The use of alcoholic stimulants during the early period of life, as practiced by the habitual tippler, causes, without doubt, serious functional and organic disease of the secretory organs, and especially of the kidneys. Dr. Bright, who first described acute nephritis, accompanied by granular degeneration, specifies intemperance to be one of the causes of this common and serious affection. Among confirmed inebriates, the organs of the body undergo physical changes tending to the perversion of their function. Thus the origin of alcoholic phthisis, of cirrhosis of the liver, disease of the membranes and substance of the brain and spinal cord and heart, and of those varied modifications of organic parts which the anatomist soon learns to observe as the devastations incident to alcoholic indulgence. The annual reports of the various hospitals for the insane in the United States ascribe intemperance as a cause of insanity second only to ill-health and pecuniary and domestic difficulties. One-third of the inmates admitted to such institutions, and in the proportion of 243, 194, and 117 to 1,000, have reduced themselves to a condition of "non compos mentis" by the use of ardent spirits. In the penitentiary of Ohio, 90 per cent. of the convicts who had been inebriates and had committed crimes, were subjected to imprisonment as the penalty; those who have charge of the young of feeble minds assert that children who have been conceived at the time the father was partially intoxicated are pretty sure to be either idiotic, epileptic, or to be feeble-minded and of irritable and nervous temperaments. How horrible the reflection that the idiotic boy or the tortured girl owe their wretchedness to the self-indulgence of the parent! It has been truly asserted that not only does such indulgence affect the health, morals, and intelligence of the offspring, but that the latter inherit the fatal tendency, and feel a craving for the very beverages which have poisoned the fountain of life, physical and moral, of the parent. Modern preventive medicine has assumed inebriety to be classed among the diseases to which man is liable, and philanthropists of every clime have founded hospitals for the relief and cure of the dipsomaniac.

In view of the fact that hundreds and even thousands of the human family perish annually from the use and effects of alcohol as a beverage and medicine, the physicians of the country, bound by the law of the code of medical ethics to warn the public of matters connected with hygiene and appertaining to their welfare, have a dread responsibility in the exercise of their authority, by example, and also by observance of strict caution as to the prescription of alcoholic stimuli—should seek to stay the destructive plague of intemperance, so often the result of the injudicious prescription of this class of stimulants. A substitute for them is found in the fluid extracts, rather than the tinctures and so-called elixirs, as recommended by Dr. Warren, of Boston. The druggists are alike responsible, since it is well known that quite a number of this class have amassed large fortunes by retailing drugs in minute forms, presented for sale and exhibited as specimens of elixirs, whose most potent ingredient is alcohol and wine—thereby increasing the public taste for stimulants. In this way has also occurred the abuse of the ethers and of chloroform. Corrupt politicians, and even the judiciary, for greed of gain and revenue, also encourage the use of alcohol; and for many years the liquor traffickers have in this and other lands controlled and shaped the legislation in Congress and in the Legislatures to complete the demoralization of society.

Finally, it should never be forgotten that alcohol, like other potent drugs, is accumulative in the system, and the effects of its excessive and habitual administration and use will ultimately expose the individual to become a confirmed inebriate.

Professor N. S. Davis, editor of the *Chicago Medical Examiner*, commenting on the fact that three hundred physicians of the city of London have lately declared the opinion that the prescription of alcoholic liquids by medical men often gives rise to the formation of intemperate habits in the patient, adds that "the medical profession are largely responsible for the evils resulting from the use of alcoholic drinks, and that the neglect to limit their use as to time and quantity is often the direct means of creating an appetite that has led many to the drunkard's goal. The custom also of speaking of such drinks as restoratives, supporting and stimulant, has impressed erroneous ideas upon the public mind; hence often no amount either of moral or legal suasion will stop the drinking customs of society, until our profession reverses its teachings and thoroughly revises its practices in regard to these agents."

In his learned treatise, "The Principles of Human Physiology," Dr. Carpenter declares :

1st. That alcoholic preparations cannot answer any of the important purposes for which the use of water is required in the system.

2d. That they do not supply anything which is essential to the due nutrition of the body.

3d. They are incapable of transformation into albuminous or fatty compounds, their alimentary value consisting merely in the power of contributing to the production of heat, though on chemical grounds, in this respect, they are inferior to fat—a fact proved by the experience of the late Dr. Kane and other Arctic explorers.

And lastly, the author asserts their action on the living body is essentially that of a stimulus increasing the vital activity of the nervo-muscular apparatus, but being followed by a corresponding depression of power, and dangerous to be used habitually.

In conclusion, it may be added that in an important paper read before the late British Medical Association at Worcester, Dr. Norman Kerr presented statistics showing all the deaths in his own practice due, either directly or indirectly, to alcoholic causes; and after carefully sifting the cases, he applied the result to the whole number of medical practitioners in Great Britain. He thus calculated that 40,500 persons died annually in that country from personal intemperance. Compared with this statement, the returns of twenty colleagues, engaged principally among the middle classes, and not including hospital or work-house cases, show a grand total of deaths wholly due to alcohol of 54,453 for 1880.

ABSCESS AND STRICTURE OF THE ŒSOPHAGUS.

BY J. H. VOIGT, M. D.,

Of Fredonia, Wisconsin.

Late in the evening of October 25, 1882, a young German woman was brought to me, a distance of fourteen miles. She was delicate and pale looking, and stated that she had not been able to eat anything for the last two days, and if she would try to eat, that it felt as if the food did not reach the stomach, and would regurgitate immediately. She stated further that she was very hungry, but perfectly well otherwise. I offered her a drink of water, which she readily swallowed, but it was immediately thrown up.

On inquiring into the cause, she related that during the first part of her first and only pregnancy she had suffered from excessive vomiting,

and at the end of the fourth month, during a prolonged painful spell of vomiting, felt suddenly something give way just above the stomach, after which some blood was thrown up, but not much. Soon after she experienced that she was unable to eat solid food, and was therefore obliged to live on soups until her confinement, April 20, 1882. During the following two weeks she could again eat a little bread and some fine-chewed meat; after which she had to live on soups again, until the 23d of November, 1882, at supper-time, when she was unable to keep anything down, not even water. She said that she only had pain when she tried to swallow solid food, when she would feel it in the back and right behind the ensiform cartilage. She had consulted several physicians, but her œsophagus was never examined, and they had prescribed for her pills or gargles, probably taking her trouble to be of hysteric origin.

I found her temperature a little below normal, and a quick small pulse, but no other evidence of a disease, and came, therefore, to the conclusion that I had to deal with stricture of the œsophagus, caused by excessive vomiting; the spasmodic contractions having probably torn the mucous from the muscular coat of the œsophagus right above the cardia; the resulting cicatrix having formed the stricture. I now tried to enter the stomach with a stomach tube, which went down readily until a little above the cardia, where it was arrested, and no allowable force could pass it further; the pressing also caused a little pain. I then took smaller instruments, until I came down to a No. 4 Engl. catheter, with its conductor nearly bent straight, which passed with some difficulty. I left it in situ about two minutes, and after withdrawing, I offered the patient a glass of new milk with an egg and two tablespoonfuls of brandy, of which she could take about one-third, taking one mouthful after another; the rest regurgitated, but she felt very much refreshed, and I told her that she had to stay in the place, and must come twice a day to my office, when I would dilate the stricture, to which she consented. The first nine days I passed the stricture twice a day with the No. 4 catheter, but was unable to pass a high number; the patient swallowed liquids with difficulty, and always regurgitated a portion. Then came two long days, when I could not make anything pass the stricture, and my patient could not even swallow water. She had for a few days already complained of horripilations and flushes of heat, and her tongue became covered with a thick brownish coat; all these symptoms now increased;

she had also thirst, an elevated temperature and a very quick pulse; it was, in short, almost a typhoid condition. On the third morning I thought seriously of making a gastric fistula, when I could again pass a No. 1 catheter; after which the patient drank a little milk. The same evening I passed a No. 2 catheter, and the next morning a No. 4, which, on withdrawing, was half filled with very offensive thin pus.

This event at once gave a different aspect to the case. I had not only to deal with a stricture, but there also was an abscess of the œsophagus. After this, I could rapidly go to the largest size catheter, which I now always filled with iodoform vaseline, and emptied the same at about the seat of the abscess. All bad symptoms gradually disappeared, and the fifth day no more pus was found in the catheter. The sixth morning I passed a small-sized œsophagus bougie; my patient could now eat thick soup and gruel, and somewhat satisfy her great appetite. Every two days I increased the size of the bougie, passing it twice a day; her capacity for swallowing increased in proportion, until at the end of the fourth week of her stay, when I had passed a $\frac{7}{16}$ -inch bougie quite easy for four days, she could almost eat anything. She had to go home then, and I told her to return after four weeks. My patient did not return until January 5, 1883, robust and healthy-looking, stating that she had been well ever since she left, and only when she would eat and swallow fast it would feel as if the food did not pass into the stomach right away, and would sometimes come back; she then also would feel a little pain at the old place. I passed at once the $\frac{7}{16}$ -inch bougie, which passed with some tightness, and my stomach tube, with $\frac{1}{2}$ -inch olive, did not pass. I therefore kept the patient and introduced the large bougie twice a day for five days, always leaving it in a few minutes, when the $\frac{1}{2}$ -inch stomach tube passed; with this I continued three days longer, after which it passed very easily. She could eat now without difficulty, and had increased twenty-six pounds in weight. The patient went home now, and I told her to return when she should have trouble in swallowing again.

In this case the mucous membrane had probably received a small rent during the prolonged attack of vomiting, as there was but little blood lost, but was evidently freely torn from the muscular coat; the rent in the mucous membrane had soon healed, forming a small stricture and leaving a cavity between the mucous and muscular coat, where the cellular tissue formed a good soil for an

abscess. Probably this case will remain cured, as the abscess seemed perfectly healed, and the stricture was small. What part the iodoform vaseline played in the healing process of the abscess, I do not know; but certainly did the daily dilatation by bougies aid in so far as it effectually evacuated the abscess and smoothed out the mucous membrane.

SOME DELUSIONS REGARDING THE OYSTER.

BY CHARLES L. DANA, M. D.,

Of New York City.

The oyster does not present a very lofty theme, and I venture to apologize first for calling attention to it at the present length.

Mr. Herbert Spencer, in his address upon America, made no reference to this interesting animal, and we are left to infer that it has no importance in American society, and no definite relation to the problems of evolution. But one may fairly claim that this is a neglect, and that he went too far in ignoring what is so unobtrusive. For the oyster represents, very typically, that absence from work and worry which should characterize the evolved life toward which Americans are advised to strive. Furthermore, the oyster, besides thus offering us certain valuable ideals, is a very considerable factor in the social life of the "R" months.

With this preamble, I venture to submit some corrections of prevalent errors regarding the mollusk in question.

First. That the oyster digests itself. For several years the statement, quite uncontradicted, has been going the rounds of the press, that the oyster digests itself. I believe that Dr. Wm. Roberts first gave currency to it. The theory is that the oyster has a large liver, which contains a diastase, and that this diastase, in some inscrutable way, digests the whole animal, under suitable conditions. Thus it has become a wide-spread belief that the oyster, taken into the stomach, does, by virtue of its liver, execute a kind of *felo de se*. Such a belief is very consoling when a person is committing midnight indiscretions with *ostrea edulis*, and it is unpleasant to be obliged to dispel it. Yet it is a fact, which the accompanying record of experiments will show, that an oyster has no more self-digestive power than a man. The hepatic diastase referred to has no power except to change glycogen into sugar—a very trivial matter. It cannot even digest the liver tissue. I have kept oysters, previously crushed between the teeth, in water (temperature 100° F.) acidu-

lated, and neutral, for hours, with no resulting digestion whatever. (See experiments iii., iv., v.) I have even dissected out the liver, and given it the best possible chance to eat itself; but neither the mystic diastase nor any other ferment at all affected its succulent autonomy. The oyster does not and cannot digest itself.

Second: That raw oysters are always more digestible than the cooked. I quite admit that the ordinary stew is less digestible than the plate of raw oysters. The stew generally contains milk, butter, and a larger number of oysters, all of which complicates the question. Half a dozen oysters, however, roasted* in the shell, or simply boiled a short time, will be digested nearly if not quite as rapidly as the same number of raw (See exper. i., ii.) Cooking coagulates the albumen, but coagulated albumen may be more digestible than raw. Thus the the white of an egg, unless thoroughly beaten, is slowly digested, and similarly, raw beef has to be finely minced in order to be quickly affected by the gastric juice. Cooking, on the other hand, loosens the tissue binding together the muscular fibrils, and allows the peptic juices to penetrate.

Third. That fermented liquors dissolve or digest the oyster. Currency has been given in the REPORTER and many other journals to the following highly instructive tale: Rev. Dr. Houghton, of Dublin, clergyman, physician and physiologist, was sitting with a friend at a restaurant. Raw oysters had been brought them. Believing, however, that it is proper *desipere in loco*, Dr. Houghton's friend ordered brandy; he himself ordered ale. Wishing to demonstrate the wisdom of his choice and the beauty of physiological processes, Dr. Houghton poured some brandy into one glass, and ale into another, and then dropped an oyster into each. The oyster in the brandy grew hard and shrivelled; that in the ale gradually melted away into a diffusible invisible solution. *Moral*: Drink ale with oysters.

Now Dr. Houghton's name and authority have great weight. I doubt if the incident related really occurred, yet it is widely circulated and credited. But it is quite as well, if one is bound to have bad and bibulous habits, to put them upon as near as possible a physiological basis. Therefore I venture to deny the possibility and accuracy of Dr. Houghton's alleged experiment, at least as regards American oysters. These grow hard in ale or beer, instead of dissolving. (Experiment vi.)

When any one becomes so dissolute, therefore, as.

*Beaumont found the difference in his single case to be only 20 minutes.

to drink fermented liquors with his oysters, he should not allow his habits to be confirmed by a false confidence in the potency of malt diastase.

The following is a brief record of experiments made:

Oyster.	Test Solution.	Temp.	Dura'n of exp.	Result.
I. Raw, masticated.	Aquæ, $\frac{3}{4}$ iij. HCl. 1 per ct. Pepsin (pure) gr. v.	100° F. to 110° F.	3½ hours.	Almost dissolved. Fine fragments and a piece of adduct or muscle left.
II. Boiled for 30 seconds.	Same solution as above.	As above.	As above.	About same result. Possible a few more fine fragments.
III. Raw, masticated.	Aquæ, $\frac{3}{4}$ iij.	As above.	As above.	Little, if any apparent change. Liver not affected.
IV. Raw, masticated.	Aquæ, $\frac{3}{4}$ iij. Sodæ bicarb, gr. x.	As above.	As above.	Same result apparently as in III.
V. Raw, masticated.	Aquæ, $\frac{3}{4}$ iij. HCl., 1 per ct.	As above.	As above.	Oyster tissue much softened; liver nearly gone.
VI. Raw, cut in to once to expose liver.	Beer, $\frac{3}{4}$ viij.	As above.	4 hours.	Oyster hardened; liver not appreciably affected
VII. Raw cut in to once as above.	Aquæ, $\frac{3}{4}$ iijss. Brandy, $\frac{3}{4}$ ss. or 6 per ct.	As above.	4 hours.	Oyster tissue a little softer.

DRAINAGE AND THE DOCTORS.

BY C. C. VANDERBECK, M. D., PH. D.,
Of Philadelphia.

In a conversation with a plumber a few days ago, he suddenly exclaimed, "What in the — does a doctor know about plumbing?" This started up some reflections, which I beg you to present to the attention of your readers.

Certainly there is a new spirit hovering over the land — reform, breathing encouragement to workers in politics, reviving energy in the ranks

of sanitary folk, manifesting itself in the demands for purity in office, in the regard hygiene is receiving, in the sturdy efforts to prevent disease by sanitation, through the teachings of the press and platform, and through the efforts of legislation. When corruption rules the land, the "*dear people*" is simply a political war-cry; when the people are truly represented, their needs are listened to and acted upon.

The plumber's query is one doubtless asked or *thought* by very many of them in these days. They are being considerably stirred up throughout the country generally, and because the doctor has told the citizens and the law-makers what he knows about the contemptibly poor, almost criminal plumbing that has been done for years and years. We may not be able to make a joint *secundum artem*, but we can tell when it is not made properly. The study of sewer-gas poisoning came not from the plumber's craft, but from the medical profession. We know a great deal about plumbing, my friend, and we propose to know more, and we intend to make bad plumbing illegal and good work compulsory.

Let us see what this movement towards *Sanitary House Drainage* may be. Among the many needs of the people, as pure water, clean streets, quarantine of syphilis, pure air and food, etc., there is a most urgent one—both in city, town, and country—both in the palatial mansion of the rich and the farmer's homestead—proper house drainage. At last it is assuming some shape whereby we can be protected from bad drainage by law. Laws regulating plumbing have been passed in New York, Brooklyn, Boston and other cities, and now Philadelphia, at last—but better late than never—proposes to fall in line.

As long ago as May 28, 1879, a bill passed the House of Representatives of the United States, by the decisive vote of 64 to 19, authorizing the appointment of an inspector of plumbing in and for the District of Columbia, and to regulate the plumbing work done in the District. While it possessed the objectionable feature of creating a new office, it certainly was tending in the right direction.

Last year Dr. Benj. Lee tried to secure a general State law for Pennsylvania regulating plumbing, but it failed at that time. He asks for the influence of doctors generally throughout the State, and in fact of other States, to secure finally a law similar to the following:

An act to establish the office of inspector of plumbing and drainage in certain cities and towns in the Commonwealth of Pennsylvania.

SEC. I. *Be it enacted by the Senate and House of*

Representatives of the Commonwealth of Pennsylvania in General Assembly met, and it is hereby enacted by the authority of the same: That there shall be appointed by the city councils, town burgesses or other legislative body, of every city, town, borough, or municipality, in this Commonwealth, which is provided with water-works or a system of sewerage, or both, on recommendation of the health officer, or where such officer does not exist, of the board of health, or where such board does not exist, of the chairman of said municipal legislative body, an inspector of plumbing and drainage for such city, town, borough, or municipality, whose duty it shall be, under the direction of the health officer, or such other officer or body as is herein above provided for, to inspect the connections of the drain-pipes of all buildings with the common sewers or with cess-pools, and the condition of the plumbing work in all houses in which cases of disease attributable to sewer-gas poisoning have occurred, or the owners or occupants of which are desirous of having such inspection made. And that from and after the appointment of such inspector no new dwelling or building shall be allowed to be occupied for any purpose whatsoever, until the said inspector shall have decided after due examination that its plumbing and drainage are perfectly secure, and shall have furnished a certificate attesting the same.

SEC. II. In all cases in which said inspector shall report that defects in plumbing or drainage or sewer ventilation exist, it is hereby made the duty of the officer or body under whose direction the inspection was instituted, to enforce such regulations in regard to said defects as shall insure their complete correction. And any person who shall neglect or refuse to comply with the requirements of said regulations shall be punishable by a fine of from twenty-five to two hundred dollars for each and every such offence, or in default of payment of fine to imprisonment for thirty days.

SEC. III. This act shall go into effect immediately after its passage.

SEC. IV. All laws or parts of laws inconsistent herewith shall be and are hereby repealed.

Dr. Lee, in his address before the State Medical Society of 1880, when urging the appointment of a committee to memorialize the Legislature, summed up his reasons as follows:

First. That much defective plumbing and drainage exists in the city of Philadelphia, even in houses which are handsomely built, of pretentious exterior, renting at high figures, and warranted by both contractors and agents to be perfectly secure in these respects.

Second. That many of our plumbers are imperfectly educated in their art, and entirely incapable of detecting faults of plumbing and drainage.

Third. That typhoid fever or typhoidal diseases existing in this city have been directly traced to defective drainage and plumbing as their cause.

Let us now see if we can discover why the plumber should taunt us with lack of knowledge of plumbing. He did not mean alone the mechanical part, but he did not see that the doctor had anything to do with sanitary plumbing.

First. It is true sanitary science is receiving more and more attention from the medical profession, but still it is a fact that it is given over too much to other set of men. The plumber and architect know this. They find that the average medical man grades his ability and standing from a therapeutic standpoint. This same doctor feels that hygiene is yet undeveloped—rather belongs to a funny set of physicians, a little inclined to “a screw loose,” etc. Is it not so? Thus we allow the honor of disease prevention to be secured by another class of men. Preventive medicine is the grand medical field of the future. There is as much honor in teaching the world how to escape the pangs of pain and the miseries of a sickroom as to introduce a new and doubtful remedy gathered from—the shade of Hippocrates only knows where. Still, progress moves onward, and it is becoming no rare thing to see a prominent medical man also a noted sanitarian. Hygiene is no longer synonymous with starve-you-to-death mountain homes. You can be a doctor of the first water and a sanitary man without a sneer—without a stigma. Such is fashion! Yes, and such is progress!

The medical fraternity is looked up to as the protector of public and individual health. Each member of it should feel it his bounden duty to promulgate the laws of health, and earnestly to plan out systems of disease prevention. Hippocrates did not despise health laws—his works abound with hygienic suggestions and treatments. Doctors as a rule are large-hearted and unselfish, curing disease as quickly as possible. Their slowness to act in sanitary matters is due to thoughtlessness and the cares of active professional life. It is hard to conceive of such a monster who would not stay the progress of disease if he could—who would chuckle over the advances of an epidemic—who can bear to hear the cry of pain and anguish. From the one who enters medicine *only* as a field of easy money-making, hygiene no doubt will get a cold shoulder. We must make money—we must live and educate our children as well as any professional men—but let us increase our income by decreasing the number of doctors “ground out” each spring, and not by retarding the progress of the noble science of hygiene.

Looking at this matter squarely and honestly, medical brother, what profession or set of men know the most about sanitary science? We are allowing a craft of workmen to demand of us what we know about hygiene. We are having the offices of inspectors of drains, sewers, plumb-

ing, and other sanitary matters, placed in the hands of men outside of our profession. We are supposed to be givers of medicine. We are called doctors of medicine, and the populace associates the word “medicine” with its limited significance—drugs. It is too bad that doctors are not more of politicians—for more than one reason. We could accomplish more for public weal before our legislative bodies, and we could secure some of the positions honestly due us. Well, at any rate, it is high time that we do not allow our sanitary knowledge to be of such a low type and of such a pacific style that we must permit a plumber or any other artisan to reproach us with “What in the ——— does a doctor know about plumbing?” It is true, we must not dictate to a practical, skilled mechanic the character of work which he should know best about; but as to the best methods of preventing the ingress of sewer-gas—of ventilation of drains, trap sewers—or in toto, the relation of house drainage to health—we do propose to know something, and demand our rights to be heard along with the plumber and architect.

I sometimes feel as if we were not yet fully aroused to the dangers of sewer-gas. The rural doctor passes it by as a subject alone interesting the citizen, and the city physician thinks it is a bugbear—a cry of the trades—a scare. If these medical brothers will spend one week’s spare time in reading up fully on the subject, they certainly will have to agree that it is the great question of the day. The sewer-gas question means pure water—pure air—pure food. It means safety on the farm—in village, city, and at the seaside. It means that diphtheria, typhoid, etc., can be better controlled.

Dr. Lee, in a late essay, sums up the effects of sewer-gas as follows:

“It is a remarkable—to my mind almost an inexplicable—fact, that members of the profession are still to be found in this county and city who deny the noxious character of sewer-gas and cess-pool emanations.”

In Europe, where experience on this question has been more extended, no doubts now remain.

Dr. J. Brown, Medical Officer of Health to the Bocup Local Board of London, has been able to trace directly and unquestionably to sewer-gas poisoning, cases of the following affections:

1. Submaxillary abscess and enlarged cervical glands.
2. Cervical abscesses.
3. Axillary abscess, with summer diarrhœa.
4. Inguinal abscess, with summer diarrhœa.
5. Facial abscess.

6. Pelvic abscess, with summer diarrhœa.
7. Multiple abscess.
8. Temporal abscess.
9. Typhoid fever.
10. Diphtheria.
11. Puerperal septicæmia.
12. Summer diarrhœa.

Those of you interested in these matters—and this is the object of my communication, to stimulate interest in hygiene—will not be able to find much of your material in classic volumes of medicine. You must seek from the various State and local health boards their reports. You must watch closely for the monographs that are noticed in your medical journals, and send for them. By the way, this is one grand object of your medical journal, keeping you fully abreast of the times. Very few works of sanitary science are published by the regular medical book houses. You will find more in the catalogues of some general scientific publisher.

Finally, I am thankful that I am writing in a journal upon whose circulation the sun never sets. I appeal not alone to Philadelphia and local doctors, but to the profession scattered over the four quarters of the earth, simply suggesting to them the claims of sanitary science, and the need of drainage even in the village—even on the farm. Take the town of 1,000 people, and what system of cleanliness have you? A mass of reeking cess-pools, privies cleaned only at haphazard, wells and cess-pools near by each other, and no end to the cases of typhoid, diphtheria, sore throat—and you wonder why these should be diseases of the country! Filth is at the bottom of most of these, and it is your duty to aid cleanliness now by legislation.

HOSPITAL REPORTS.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER.

Reported by W. H. Seelye, A. M., M. D.
Asthma.

Patient's name is Chas. V. Age 39. A German by birth. Occupation, a book-seller. Physically, of medium height, large frame, and heavy. Complexion light, with blue eyes, and thin sandy hair and beard.

History.—His father, he says, died suddenly, at the age of 68, of heart disease and the rupture of a blood-vessel, which was probably an aneurism or apoplexy; and he had always suffered from hemicrania. His mother is still living, but is very nervous and subject to frequent hysterical attacks. The patient was the fifth one of nine

children. Up to within the last four years he was accustomed to drink a good deal of beer, but since then he has been more moderate. He has also used tobacco to excess. Except for a chancre seventeen years ago, he was never sick before he came to the United States. He lived in St. Louis until the last year and a half, and while there he had his first attack of rheumatism, which lasted three months. Last winter he had a second attack in the knees. Last June he was employed as a book-seller in a publishing house in this city, where the air was impure and damp, and the ventilation was poor. At this time he began to lose his appetite, and he found that his nose itched and his eyes became dry, and he sneezed frequently. Soon he noticed that he coughed and became short of breath on exertion, and he expectorated large quantities of frothy mucus. Before long he noticed that these attacks of asthma occurred only in the morning after breakfast, and at about eight o'clock; and that they recurred at the same time every day while he remained in that building. He was not troubled with dyspnoea at all during the rest of the day. But soon the attacks became more frequent and violent, so that he was obliged to give up his work. He found then that in pure air he was almost free from dyspnoea. For several years before this he had been somewhat short of breath, but he had never had any other nervous trouble. Last Friday a severe attack of asthma came on, which he found that smoking cigarettes, his usual remedy, did not relieve. So on Saturday he came to the hospital for treatment.

Remarks.—Gentlemen, the first step at the bedside is to get the past history of the patient and his family, if possible. If he is intelligent, he will tell you this clearly himself; but if he is not, it will be necessary to elicit it by questioning him. This you will sometimes find to be a difficult process, and you will have frequent opportunities for observing the different degrees of perspicuity in the minds of patients, from their ability to make a clear statement of facts. You will therefore have to examine and cross-examine them, and learn all you can besides, from their friends. It is necessary to make yourselves familiar with the subjective phenomena of disease as well as the objective, which you can observe for yourself; and the subjective history often includes the history of the patient's family,—for every individual is a link in a very long family chain, and many of the diseases, which will fall under our observation, have an important hereditary history. You will also find, on studying the history of diseases, that there are certain correlative affections which though apparently different, are connected together by a common cause, and manifest themselves in one form or another in succeeding generations. The history of this patient, therefore, opens with two very important facts, viz.: that the father died suddenly from apoplexy or heart disease, and had previously been subject to hemicrania, while the mother, still alive, is nervous and hysterical. These two ancestral conditions bear directly on this man's nervous trouble.

Having now completed the subjective history, we come to the objective examination of the patient. As you see him at present, he does not present the favorable conditions for study that he

did when I first saw him, soon after his admission into the hospital. He was then suffering from an asthmatic paroxysm, and I found him sitting up with great orthopnoea, his lips and cheeks swollen and puffed out, and he had great distress in breathing. Dyspnoea was the most prominent objective symptom, and you would all have said, it was evident that his trouble was located in the chest. For those who have had little experience in diagnosis, the reason why it is so difficult for him to get air enough can only be ascertained by making a physical examination.

Inspection.—Place the patient first on his back, or in that position which will be most favorable for inspection—and so also for all other physical examinations. Observe now that his face is congested, his eyes prominent, and his lips distended, and his breathing is difficult and labored. On sitting up he is more comfortable, and you see that his breathing is mostly done by the diaphragm and the abdominal muscles. The chest moves symmetrically on both sides. I suppose you all know the possible causes for dyspnoea. If you do not, you should look them up, and carefully study dyspnoea as a symptom. As the patient breathes, the forcible exit of the air from his mouth is plainly audible. He coughs frequently, and expectorates large quantities of a light greenish, frothy sputa.

Palpation.—First, I place my hands over the anterior and upper part of the chest, and now I can easily appreciate the symmetry or want of symmetry in the expansive movements of the two sides. I find them symmetrical in this case. Now I place my hands on the sides of the chest, and on his taking a full breath I get a symmetrical motion.

I will next examine the chest, to find out whether or not the density of the lungs on the two sides is at all modified. To appreciate this or any other pathological fact, we must know the action of the organ in health. The object of percussion is to see if there is any difference in the density of the lungs on the opposite sides of the chest, or in different portions of the same side. Percussion may be either mediate or immediate, and there is a right and a wrong way of performing both. Cultivate delicacy of touch, and do not “thump a thorax.” Forcible percussion is sometimes necessary, but this does not mean that you must pound the patient with your fist. Delicate percussion is as a rule, I think, more useful than heavy. Mediate percussion consists in striking upon some medium placed over the region to be examined. Immediate is applied directly upon the surface of the body. The mediate method is the most common. The medium percussed is ordinarily the finger of the examiner, though many are accustomed to use a pleximeter of hard rubber or other material, and this is tapped upon with a hammer or the finger. The fingers are preferable, because they dispense with the necessity of carrying around so many unnecessary instruments, and the results obtained are perfectly satisfactory. It is a good plan to place the patient against a door or other object which acts as a sounding-board, and intensifies the effects of the percussing. This we cannot do in this case.

Percussion.—First, by the mediate method, the resonance is found to be about normal and sym-

metrical on both sides of the chest in front. The same conditions prevail behind, with a slight difference in favor of increased resonance on the right side. Percussion under the axillæ gives the same result. There is no apparent difference then in the two lungs as regards density, by mediate percussion.

Immediate percussion, by slapping the back with the palm of the hand, elicits likewise no variation of sound on the two sides. Where the patient is very fat or the muscles unusually large considerable force is necessary, but delicate percussion usually answers every purpose.

It still remains to examine the patient's breathing, by the ear. And this, too, may be done either immediately or mediately. The mediate method is by the use of the stethoscope, and the immediate is by the direct application of the ear. It is better to cultivate the latter method first. But many students begin at once to use the stethoscope. The most information is obtained by the direct application of the ear. And this is the best method for examining the lungs; but, in examining for heart disease, the stethoscope is indispensable, for by it small localized areas may be more accurately examined, as it shuts off neighboring sounds.

Auscultation.—On applying my ear in front, over the right chest, I hear no clear respiratory murmur, but there is a complete absence of the inspiratory sound: and it is as if the time of inspiration was represented by zero. I hear no air entering the lungs. The expiratory sound is slow, and prolonged, and feeble. If I were to listen behind, I would probably hear the air entering the lungs, and the coarse whistling rales characteristic of asthma; and, at the base of the lungs, coarse moist rales associated with dry sibilant rales.

As the result of our examination, we conclude that this is undoubtedly a case of asthma. But the question arises next, is it simply uncomplicated asthma? On account of the large amount of his expectoration in the twenty-four hours, and from his constant cough, and the presence of moist rales, we conclude that he has a bronchial catarrh added to his asthma.

This catarrh is probably located in the large ramifications of the bronchial tubes. The man's distress of breathing is not as great as when the action of the lungs is interfered with by a catarrhal process in the minute ramifications of the bronchial tubes. There is no collapse of the air-cells, but the air is freely admitted to them; and there is a little emphysema, shown by the slightly increased resonance of the chest. And in this connection, if you do not know what emphysema is, and all about it, find out, and see how many varieties there are, and their cause and symptoms. I have often thought that it would be a good thing for the student, if a course of lectures were given on the symptoms of disease, rather than on diseases themselves. Lectures on the prominent symptoms in a great variety of diseases, would form a very valuable part of any didactic course of lectures, in our medical colleges.

As we have seen, then, the physical examination of this man shows that he is suffering from asthma, which is a spasmodic affection of the muscles of the bronchial tubes; and as complications,

he has bronchial catarrh, and slight emphysema.

This does not complete all the interesting points in this case, but it is all that we have time to consider to-day. I may call your attention to this case again, at our next meeting, in the hospital wards, and then I will bring out some additional points concerning asthma.

MEDICAL SOCIETIES.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, January 11th, 1883. The President, Dr. Tyson, in the chair.

Condylomatous Tumor of the Labium.

Exhibited by Dr. Nancrede for Dr. C. M. Seltzer.

Mrs. ——— contracted syphilis nine years ago from her first husband. Has had specific treatment at intervals, but never prolonged beyond a few weeks each time. Condylomata and ulcerations around the vulva, anus, and perineal region were first noticed about three years ago. She first came under my observation and treatment June 1, 1882, at which time symptoms of her disease were very pronounced, such as cachexia, nervousness, nocturnal headache, ulcers on various portions of the body, numerous condylomata, of which the specimen exhibited was the largest, being a cauliflower-like excrescence springing from the left labium majorem, having a pedicle about $2\frac{1}{2}$ inches broad. The clitoris was hypertrophied, forming a knob one inch in diameter. There was urinary incontinence, and consequently severe excoriations of the external genitals. Potass. iod. and hydrarg. bichlorid. were given, upon which there was pronounced systemic improvement. Local treatment failed to remove the condylomata, hence on the 13th of November, two double ligatures were passed through the pedicle of the largest, so as to divide it into three parts; then tied tightly and the mass removed, and the stump cauterized with nitric acid. The clitoris was so sensitive, even under profound anæsthesia, that it was thought best not to remove it. The patient made a good recovery in 10 days, including the cure of the urinary incontinence. Her second husband, to whom she has been married about six years, has no evidence of having syphilis. Her only child by her first husband has stricture of the rectum and obstinate fissure of the anus—improvement of which only began upon the recognition of their specific origin, and the consequent line of treatment.

Dr. Nancrede suggested the reference of this specimen to the Committee on Morbid Growths, since two somewhat similar specimens had been presented by Drs. Formad and Baer, which were myxomatous fibromata, although not due, as in the present instance, to the irritation of some sore or abrasion by the discharges, etc., in a syphilitic, yet probably their histological structure was identical.

Small Tumor of the Head of the Pancreas.

Presented by Dr. E. T. Bruen.

The mass here exhibited occupies the head of the pancreas, and is about as large as a

pullet's egg, or about two and a half inches in diameter. When removed from the cadaver, it was closely adherent to the common bile-duct. The growth is of a colloid nature, but its histological character is as yet unsettled by microscopic examination. There were no secondary deposits in any other viscera, as is the rule in colloid growths. The patient was a male, æt. about 65 years. For two years prior to date of his death, there had been intermittent attacks of jaundice. This had been attributed to catarrh of the biliary duct, which had developed itself during an attack of malaria. The case was under my care for two months. At first the symptoms of chills and fever led to treatment for malaria; but as the jaundice gradually deepened, treatment for the supposed catarrhal state of the bile-duct was instituted. The futility of a well-directed and usually successful treatment was the special indication of some more substantial cause. Hepatic trouble or biliary calculi were readily excluded in this case, but there was nothing to fasten suspicion on the pancreas. There was constipation, with clay-colored stools. There was a febrile movement of the hectic type—the so-called hepatic fever, accompanied by irregular chills. The intestinal indigestion, so valuable a symptom in many cases of pancreatic disease, was not marked.

Indeed, without exception, the negative results of the clinical record are of the most discouraging character. The case is presented because each case of pancreatic disease ought to be recorded, so that many cases viewed collectively may contribute to the clearness of a future distinct picture of pancreatic disease.

Dr. Formad said that he had now on record the notes of five or six cases of cancer of the pancreas with marked jaundice, where he had made the autopsy. It seemed to him that the jaundice was most persistent in primary pancreatic carcinoma from pressure on the bile-duct. He was present at the autopsy of this case, and did not think that the tumor was carcinomatous, as there would then probably have been secondary growths in the liver. The growth was probably a cystic colloid.

Dr. Bruen would like to call the attention of the Society to the fact that he had about a month ago presented a specimen of carcinoma of the pancreas, and had then referred at length to some forty cases of jaundice due to primary carcinoma of the head of the pancreas, lately reported by another observer. From these records it was demonstrable that jaundice was an invariable symptom of primary hard carcinoma of the head of the pancreas, while it was uncommon when the disease was secondary or affected other parts of the organ.

Diaphragmatic Hernia.

Exhibited by Dr. Jas. Tyson.

The patient from whom these specimens were removed was a German, between 27 and 28 years of age at his death. He first consulted me on June 21, 1880. He had been ailing since February, 1878, and had been unable to work in that time. At the date referred to he was stretching, when his wife suddenly pretended to tickle him. He quickly threw down his arms, and at that moment felt a sensation of "pain on the left side in the neighborhood of the heart." At the same time he felt faint and cold. In five or ten minutes

these sensations passed away, but he remained very much frightened. When he first visited me, he complained of shortness of breath and beating of his heart, although the latter was better when he was quiet. He could not even walk across the floor without becoming completely out of breath, but he said he was not short of breath when the accident first occurred. He had also a peculiar puffing respiration, which did not occur, however, with every act of expiration, but once in four or five. This was so characteristic that one of my friends, to whom I sent him, spoke of him as my "puffing German." There was no cough. Physical examination revealed on inspection almost total absence of movement of the chest wall in the upper half, the respiration being almost purely abdominal. The upper percussion border of the heart corresponded with the junction of the third rib with the sternum, and the right border with the middle of the sternum. The apex beat was in its normal position, but was more diffuse than in a strictly normal state. Pulmonary percussion appeared normal except below the left scapula, where resonance was less than in the corresponding situation in the right side. Vocal fremitus was however impaired over the whole of the left lung. There were no abnormal cardiac murmurs. His pulse was 72 after the examination was over. He was treated at various times with digitalis, bromide of potassium, chloral, tonics, etc., and even a blister was put over his heart, with the view that there was some cardiac or pericardial affection, although the physical signs were wanting. There was no improvement, although at times the dyspnoea, which was the most distressing symptom, seemed somewhat less; but it always interfered with any exercise whatever. He would walk sometimes half a mile with great difficulty. Notwithstanding this, he was encouraged to take exercise. His sleep was unsatisfactory, he would dream and wake up in a great fright. He could always lie upon his left side with more comfort than upon his right. He continued under my observation for a year. I saw him in the latter part of August, 1881, when he seemed a little better. After that I heard nothing of him until I learned of his death, which occurred December 15, 1882, from obstruction.

At the autopsy it was ascertained that about 20 inches of the large intestine, with its corresponding mesentery and almost the whole omentum, had ascended through the œsophageal opening of the diaphragm into the left pleural sac, encroaching upon the space occupied by the left lung, until the latter was compressed into the apex of the left pleural sac, and was reduced to a cylindrical mass about 15 centimetres in length and half as many in diameter. There was no hernial sac, the opening being that for the œsophagus. The case would therefore be technically called one of hernia diaphragmatica spuria. The heart was displaced to the right, but was otherwise normal; the liver was slightly fatty; but the other viscera were normal. It is not unlikely at the moment referred to in the history when the patient threw down his arms, that a small portion of the omentum or mesentery slipped through the œsophageal opening, and that subsequently and more or less gradually the vacuum tendency of the pleural sac in each act of respiration caused the

remainder of the mass to be drawn in until the entire cavity was occupied. This accounts for the fact that there was no dyspnoea at the beginning, but that it gradually increased as the thoracic space was intruded upon. In vol. 81, 1882, of Virchow's archives, will be found an exhaustive article on diaphragmatic hernia, in which 291 cases are collated. In a somewhat hasty examination of this paper, I have been unable to discover a single case so long under observation as this—nearly four years. Many cases were discovered at the autopsy and had been unsuspected, others were congenital, and others were traumatic. Dr. Formad related some facts confirmatory of the history given by Dr. Tyson. Dr. Bruen asked if there had been any hiccup! If so, was there any dysphagia with solid food? Finally, did the physical signs suggest pneumothorax? Dr. Roberts made some remarks with reference to the diagnosis and to the possibility of laparotomy in similar cases. He also asked whether the symptoms just preceding death were those of strangulation. Dr. Davis referred to thirst as a prominent symptom according to Lawrence. Dr. Tyson replied that Dr. Formad had told him that there was decided hiccup. There was no true tympany with the absence of the vocal fremitus. Nothing gave rise to any suspicion of its true nature. Thirst was marked. There was no dysphagia.

Ulcer of the Stomach in the Anterior Wall; Adhesions to the Abdominal Wall; Hemorrhages and Pain: Death from Morphia Habit.

Exhibited by J. H. Musser, M. D.

I am indebted to Dr. J. Henry Musser, of Lancaster county, for the privilege of presenting this specimen. I abstract from his notes the following history: I. J., aged 71 years, millwright. Fourteen years before his death he was attended by the doctor for hæmatemesis occurring after three days of nausea. Over a pint of blood was vomited, and considerable was discharged by stool the next day. In ten days he returned to work and enjoyed good health for two years, with the exception of occasional attacks of indigestion. Then a recurrence of nausea, followed by a profuse discharge of blood, per anum, occurred. He made a full recovery, but pain after eating was now noticed. Two years subsequently he bled very much from a wound of the foot, and was much prostrated thereby. This was succeeded by severe pain after eating, with marked epigastric tenderness. The constant use of narcotics alone gave him relief. November, 1873, he was again under Dr. J. Henry Musser's care, and was treated for gastric ulcer without any avail, save when he exhibited narcotics. He resorted to the use of morphia, and continued its use during the remainder of his life. Change of diet did not influence the pain, and he partook of laborers' fare. In 1877, a small tumor to the left of and several inches above the umbilicus, hard, tender and apparently involving the abdominal wall, was discovered. For several years he worked in a country saw-mill, using one drachm of morphia a month. Heavy lifting aggravated his pain. August, 1882, the doctor was again called in, to find the patient confined to bed, much emaciated and with complete anorexia. Death took place three weeks later, during which time he had taken no nourish-

ment, but had used morphia freely. The habit had been acquired, and his friends thought he suffered but little pain. The only anatomical alteration noted at the autopsy was the change in the stomach. The organ was enlarged and contracted (hour-glass) towards its fundus. The anterior wall, one-third of the distance from the fundus, and at the point of constriction, was adherent to the abdominal parietes to the left of the median line, three inches above the umbilicus. Opposite to the point of adhesion in the mucous membrane there was a small ulcer two lines deep and six in diameter, with clean-cut edges, a healthy floor, and surrounded by cicatricial tissue for a radius of one inch. Undoubtedly the ulcer would have healed entirely had not the morphia habit cut off the patient.

Remarks by Dr. J. H. Musser. It is plausible to theorize that the first hemorrhage, taken with the profuse foot hemorrhage, was due to the patient having been of an hemorrhagic diathesis, and that the second gastric hemorrhage was from the same cause, and was attended by a hemorrhagic infarct with subsequent development of the ulcer. Especially is this possible as it was only after the second hemorrhage that pain occurred, and this symptom is never absent, "except in cases which run a rapid course." [Da Costa.]

Dr. Nancrede related the case of a "bleeder" then under his care, a female infant only thirteen months old, where death was imminent from epistaxis.

Dr. Dunn made some remarks on the general subject of hæmophilia and its treatment.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Heart-Puncture and Heart-Suture as Therapeutic Procedures.

BY JOHN B. ROBERTS, M. D.

[Read January 3, 1883.]

It is more than probable that, in a few years, puncture of the heart-wall (cardicentesis), with direct abstraction of blood by aspiration, will be recognized as the best treatment in cases of greatly dilated or much distended right heart, with intense pulmonary engorgement; and that incision of the pericardium with suture of the heart muscle will be accepted as proper in cardiac wounds. Hence these latest novelties in cardiac surgery deserve the attention of the Fellows of the College.

That punctures of the heart are comparatively harmless has been well known to many for some years. In 1872, Roger, while performing pericardicentesis on a child with pericardial effusion, thrust the needle into the right ventricle and withdrew about $6\frac{1}{4}$ Troy ounces (200 grams) of pure venous blood. The boy, who was aged five years, became pale, sweated, and had an imperceptible pulse. The withdrawal of the pericardial fluid, accomplished prior to the heart injury, was beneficial; and the cardiac puncture did no permanent mischief, for the patient recovered. Death occurred five months later from long existing dilatation and valvular disease of the heart (*Bull. de l'Académie de Médecine*, 1875, p. 1276).

In Hulke's case (*Trans. Clinical Society of London*, viii. p. 169), a woman with pleuro-pneumonia was supposed to have large pericardial effusion,

and a trocar was introduced through the fourth left intercostal space. Nothing escaped except a drachm of venous blood, after which the patient seemed relieved of dyspnœa. She died four weeks later from a complication of diseases, and the autopsy revealed cardiac dilatation and valvular changes.

I have said elsewhere (*Paracentesis of the Pericardium*, 8vo., Philadelphia, 1880), in commenting upon this case: "The abstraction of blood seemed to relieve the distended heart much better than phlebotomy would have done, as was evinced by the diminution of threatening symptoms and the decrease of the area of dullness."

Cloquet, Bouchut, Legros, and Onimus have also observed the apparent innocuousness of wounds of the heart made by capillary trocars. Steiner found, ten years or more ago, that electro-puncture needles could be quite safely introduced into either ventricle, provided they were at once withdrawn (*Medical Times and Gazette*, May, 1873, p. 492 from *Langenbeck's Archiv für Klin. Chirurgie*.)

It has been considered less safe to puncture the auricles; but the interesting paper of Dr. Benj. F. Westbrook, just published in the *Medical Record* for December 23, 1882, seems to show that our fears are as unfounded as were those of our predecessors in regard to ventricular puncture. It is, in truth, to call attention to his case of harmless intentional cardiacentesis and to his researches in the surgical anatomy of the operation, that I have been led to refer to the corroborative evidence of the cases mentioned above.

I have with much satisfaction, as have many others, done venesection at the bend of the arm for the temporary relief of the distressing symptoms of dilated heart, and for the dyspnœa due to the pulmonary engorgement of acute pneumonia. If, however, a few drachms of blood drawn directly from the heart give the relief that could only be afforded by taking a similar number of ounces from the veins of the arm, it seems proper to adopt the former measure. The subsequent circulatory depression from anemia would undoubtedly be less than after the latter operation.

It is manifestly necessary, however, to determine that cardiacentesis is innocuous, before it can take the place of venesection. The above-mentioned cases and Dr. Westbrook's experience tend to show that such is the fact.

Dr. Westbrook believes that the proper place to perform the operation is in the third costal interspace, close to the *right* edge of the sternum. This situation enables the operator to tap the right auricle without injuring the right internal mammary vessels, and with little danger of striking the tricuspid valve. My own preference would be to perforate the ventricle of the right heart by introducing the needle through the fourth interspace, about one and a half or two inches to the *left* of the median line of the sternum. Dr. Westbrook's opinion, however, is entitled to more deference than mine, because he has studied the subject with special reference to cardiacentesis, while my special investigations have been limited to the consideration of pericardicentesis.

Further experimentation in heart-puncture for the relief of cardiac distension and pulmonary en-

gorgement is requisite, but it is probable that it will soon become a well-recognized surgical procedure in selected cases. Pericardicentesis has already taken that position, and there is no reason to believe that cardiac surgery will stop its march with the demonstration that the pericardium can be treated as the pleura.

In October, 1881, I read a paper before the Anatomical and Surgical Society of Brooklyn (*The Surgery of the Pericardium; Annals of Anatomy and Surgery*, December, 1881), in which I advised resection of costal cartilage and incision of the pericardium for removal of foreign bodies in the pericardial sac; and at the same time said: "The time may possibly come when wounds of the heart itself will be treated by pericardial incision, to allow extraction of clots, and perhaps to suture the cardiac muscle."

It seems as if this time had now almost arrived, for Dr. Block has not only expressed a belief that death can be averted in many cases of heart-wounds by simple incision of the pericardium to allow escape or extraction of the clots which cause pressure and death, but has also undertaken to demonstrate by vivisectional experi-

ments that suture of the heart is a simple operation, and requires but three or four minutes. *Amer. Journal of the Medical Sciences*, January, 1883, p. 276; from *Journal de Méd. de Paris*, October 28, 1882; from *Gaz. Méd. de Strassburg*, October 18, 1882). He finds that opening of the right and left ventricle, and entire compression of the heart for the application of sutures, can be supported by rabbits for several minutes. During suturing, he seizes the apex of the heart and draws the organ forward until the traction prevents the escape of blood from the wound. Sutures are then introduced, or the orifice closed by ligation. Even if cardiac pulsation and the respiration stop during this mechanical interference with the heart's movement, death, he asserts, does not necessarily ensue.

These experiments are even more important than the researches spoken of in regard to heart-puncture. I regret that as yet I have not been able to consult Dr. Block's original memoir, but I hope at a future time to do so, and perhaps to be able to report some investigations of my own which I desire to make in the same direction.

EDITORIAL DEPARTMENT.

PERISCOPE.

Removal of Uterine Appendages for Arrest of Hemorrhage.

It is now just ten years since Lawson Tait (*British Medical Journal*, Dec. 30, 1882) introduced the operation of the removal of the uterine appendages for the arrest of hemorrhage. At first the ovaries alone were removed, but it was found by experience that the results were more speedy and satisfactory when the tubes were removed. Increased experience, says Tait, has taught me that it is with the tubes that we have chiefly to do, and that the function of menstruation has little or no dependence on the ovaries.

If the tubes are removed and the ovaries left, menstruation may be entirely suspended.

Two cases of bleeding uterine myoma are cited of exactly parallel nature. In the first case, the woman would not consent to the operation. She married in June, and died of hemorrhage in August.

In case second, the patient submitted to removal of the appendages, and made a speedy recovery, regaining perfect health.

The hemorrhage in both these cases was caused by uterine myoma, in each of which it was enucleated with but little amelioration of the symptoms, as the growth soon returned. From a study of these cases we learn that a hemorrhage due to a myoma may be fatal; that the secondary results of enucleating are not gratifying, and also the high primary mortality of the proceeding.

Mr. Lawson Tait has published a series of cases

which prove, "That the primary mortality of the removal of the uterine appendages for bleeding myoma is very small, and is limited to those cases already so reduced by loss of blood as to be practically unable to stand any surgical proceeding—that the secondary results of the operation are extremely satisfactory, and are permanent, the arrest of the hemorrhage being followed by the shrinking of the tumor, and in many cases by its complete disappearance."

It is said that this operation deprives a woman of her sexual powers; this is, however, not the case; but granting it to be true, nothing could be more immoral than to refuse to relieve a suffering woman on such a plea.

Another objection to the operation is that it destroys the possibility of impregnation; but it strikes us that as the chances of a womb in which there is a myoma being able to contain and nourish a fetus are infinitely small, the fact of the woman becoming pregnant is placing her life in jeopardy.

Lithotomy in Children, and the Advantages of a Long-Beaked Staff.

Dr. J. Ward Cousins read the following at the last meeting of the British Medical Association. (*Brit. Med. Jour.*) Lateral lithotomy in children with a special modification of the ordinary staff, can be made easier of performance, and many of the common difficulties of young operators can be avoided.

The staff is a modified rectangular staff, with a rounded-off angle, and a long beak, and the point

slightly turned upward. The lateral groove commences half an inch above the angle, and terminates about the same distance from the point. The main peculiarity is the length of the beak, and this varies regularly with the size of the staff.

The Shortness of the Angle permits the instrument to be easily felt, and so assists the operator in making the deep perineal incision. As soon as the angle is exposed, he readily learns by the finger the point of the staff he has reached. When the finger enters the groove, the position is indicated exactly by the part of the nail engaged in it. The point of the finger-nail informs the operator he is on the angle; but, directly the side of the nail is well insinuated in the groove, he can be sure that he has reached the beak, and that a simple movement of the knife will open the bladder.

The Beak is nearly straight, and is fixed at a Right Angle in the Staff.—When the instrument is held firmly in position under the pubic arch, the floor of the bladder is steadily depressed; at the same time the beak is parallel to the rectum, and so protects that organ from injury. The horizontal beak forms a straight guide into the bladder, and a straight movement of the knife in the groove is very readily and safely accomplished.

The Long-Beak.—This part of the staff enters the bladder a little more than an inch, and is kept in contact with the stone. The long-beak affords important advantages, especially in operations upon children; for, during early life, the urethral structures are more soft and delicate, and the bladder is situated high up behind the pubic arch. It is a simple safeguard against one of the most common and painful accidents which occur during lithotomy, as the point cannot be pushed out of the bladder.

Lastly, the long beak renders the introduction of the finger into the bladder over the staff both easy and safe. The upper concave border of the staff is the best guide to the stone in all operations upon children; for not only is the upper wall less prone to shift under the finger, but by gentle pressure in this direction, the bladder is brought down, and its neck very readily dilated. It, moreover, effectually prevents the operator from slipping the finger into the areolar tissue of the recto-vesical space, which has often been mistaken for the interior of the bladder itself.

The Inoculation of Syphilis.

The *Lancet* says: "A few weeks ago we directed the attention of our readers to the interesting observations which have been made in Germany, of the frequent association of bacteria, fairly definite in characters, with the tissue changes produced by syphilis; and we pointed out that the relation between the organisms and the disease cannot be more than probable until culture experiments and inoculations shall have given some positive results. The subject has been further investigated by a French syphiligrapher, M. Martineau, but it may be doubted whether it has been advanced by his researches. His search for organisms in the blood, chancrous induration, and cutaneous manifestations of the disease, has been fruitless, but another method of procedure has led to results which he regards as more definite. A recently-

excised chancre was placed in a closed vessel which had been previously heated to a red heat. A concentrated 'bouillon' was prepared and boiled for about two hours. It was then placed in a flask with a long neck, the temperature was lowered to 30° C., the chancre was introduced, and the neck of the flask was sealed at the lamp. The liquid was found, next day, to contain numerous bacteria of a special form, and a day later some of it was injected into the peritoneal cavity of a pig five months old. In a month seven or eight prominent papules appeared on the abdomen, followed by others. A few days afterwards conjunctivitis appeared in one eye, and a tumor on the penis. For the sake of comparison another pig was inoculated with pus from a syphilitic chancre, with the result of causing an eruption exactly similar to the first. Some bacteria were found in the blood of the second animal, and were injected into a third pig, a goat, and a monkey, but without result. The blood of these animals presented no bacteria. M. Martineau thinks that the cutaneous affection observed on the first two pigs presented the characters of a syphilitic eruption, and he concludes that syphilis is transmissible from man to the pig, but not from it to other animals, nor to other animals from man—a conclusion for which the facts of his experiments certainly give him only the most slender basis. His operations are to be reported on by a committee composed of MM. Bouley, Pasteur, Fournier, and Lancereaux.

Tubercle of the Choroid.

The *Medical Times and Gazette* says: The debate on the relation of tubercle of the choroid to tubercular meningitis at the Ophthalmological Society, was of interest both to ophthalmic surgeons and to physicians. It is not so very many years since the possibility of the recognition of tubercles by the ophthalmoscope was, to say the least of it, doubted. The point that was really in debate was raised by Dr. Warner, viz., is tubercle of the choroid more likely to be found in cases of acute miliary tuberculosis where there is no meningitis than where this is present? The case which he detailed to the Society was an instance in favor of the former hypothesis. It may be said at once that the views of all the speakers tended in the same direction. Now, if it is a fact that choroidal tubercle is rarer in cases with meningitis than without, there must be some good reason for this, and we hope that those who have the opportunities will set to work to discover it. The only explanation which occurs to us is that the deposit of tubercle in the choroid in a case of acute miliary tuberculosis is a late occurrence, and that in the majority of cases of tubercular meningitis the patient dies before the tubercles have had time to appear in the choroid. We do not say we believe this ourselves, but it is a plausible explanation, and it is one which can be verified or not by careful statistics.

To revert to the original question, for ourselves we venture, with all deference to the majority (if not, indeed, to all) of those who took part in the debate, to think that there is no connexion whatever between choroidal tubercle and acute miliary tuberculosis without meningitis; we can see

nothing more than a somewhat unusual coincidence.

Before giving our reasons for this opinion we would make one general remark, that will do away with some of the objections to our views that might be based on the remarks of some of the speakers at the debate. We consider that a negative examination during life, even when made by an ophthalmic surgeon of the utmost skill, is by no means a proof of the non-existence of choroidal tubercle, and we would not accept any statistics relative to their presence or absence that were not based on post-mortem examination. Of course, in cases where a microscopical examination is made, this affords the most conclusive evidence; but we have generally found it sufficient to strip the choroid from the sclerotic, and examine the supposed tubercle from behind, when, if real, it will be found to present the same grey appearance that it shows in the pleura or elsewhere. If we were to leave out of consideration the remarks of Dr. Barlow and Dr. Coupland, we should be led by the rest of the speakers to the belief that tubercle in the choroid was an exceedingly rare occurrence. This we attribute mainly to the fact that they were speaking from a clinical, and not from a pathological point of view.

Developmentally, the choroid is the homologue of the pia mater and the other serous membranes; there can, therefore, be no *à priori* reason why tubercles should not occur there. We all know that tubercles are much more likely to be found at the base of the brain than on the convexity, but we do not know the reason of this; and in the same way we do not know the reasons why tubercles are not found in the choroid in every case; but our own limited experience leads us to believe that they are much more common than is generally supposed. We should say, for instance, that they are decidedly more common in the choroid than on the pericardium. It seems to us that, in the debate, clinical and pathological evidence were mixed up in a manner that was hardly fair, though, of course, quite accidental. Thus, those who spoke of the extreme rarity of choroidal tubercle in tubercular meningitis were referring to clinical experience, whereas those who spoke of choroidal tubercle in general tuberculosis without meningitis were obviously referring to post-mortem evidence. It is hardly necessary to point out what a difference this makes.

Congenital Keratomatous Degeneration of the Epidermis.

At a late meeting of the New York Medical and Surgical Society (*New York Medical Journal and Obstetrical Review*), Dr. G. G. Wheelock showed the body of an infant that had recently been born at the Nursery and Child's Hospital. Labor was protracted, there was inertia uteri, and the House Physician sent for Dr. Wheelock, saying there was an abnormal feeling about the child's head, and it was probable instruments would have to be used. When Dr. Wheelock arrived the woman had been in labor about thirty hours; the cervix was about two-thirds dilated, its tissue being rather thick and oedematous. The head presented, but the position could not be determined. The surface of the head was rough and granular to

the touch, and reminded one very much of the feeling of carious bone. There was no hair, and the sutures seemed to be so numerous that their individuality could not be recognized. The head was drawn down to the vulva by the forceps, and delivery was completed with the hand. It was difficult to extract the head, on account of the chafing of its rough surface against the soft parts. At birth the child appeared dead and macerated, and he regarded with surprise the House Physician's statement that an hour before it was alive, and the pulse beating 140 a minute; but in a few moments the child breathed, and continued to live for six hours. On first looking at the child, the appearance of its skin suggested that of an alligator or an armadillo. The epidermis was thick and horny, and, being divided by fissures, seemed to be composed of large and small-sized plates. Between the plates on the abdomen the true skin beneath could be seen as a raw, red surface. The ends of the fingers and toes projected through the horny skin. The condition presented corresponded very closely with that of a similar case reported by Sir J. Y. Simpson, which he called congenital or intra-uterine ichthyosis. Dr. Wheelock, however, thought it might more properly be classed as a keratoma. Simpson had collated eight cases, and a Boston physician had known of three in one family. Four were to be found in recent German literature. In the present case there was ectropion of the upper lid of the right eye; the eyes were normal. Thick skin gave the nose a flattened appearance. The external genitals (the child was a female) appeared to be perfectly formed. It was the mother's first child. At the post-mortem it was found that the lungs could be inflated only partially, and they scarcely floated in water. There were hæmorrhages in various parts of the brain, and quite a large one was found in the posterior part of the left lobe; there was great congestion in both ventricles. The kidneys were normal, except that they were very much congested. The liver, also, was very highly congested. The mother was perfectly healthy, and gave no syphilitic history. The same was true, so far as was known, of the father. It would seem that the condition of the skin determined the blood to the internal organs, all of which were found much congested, and thus caused death. In reply to a question by the President, Dr. Wheelock said that in several of the cases reported by Simpson, life continued fifty or sixty hours, but in none over four days. The President had seen this case with him, and had reminded him that the condition was such as had been described by Simpson.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—As far back as 1870, Dr. Arthur E. Spohn, of Corpus Christi, Texas, used elastic rubber-ring tourniquets, and at various times since has brought their advantages to the notice of the

profession through different medical journals. The advantages he has derived from them are so obvious that his experience and methods should be studied by those who would employ this effective and painless means to control hemorrhage. Reprints may be had by applying to him as above.

—Mr. Frederick Treves' essay on "Scrofula and its Gland Diseases," has been reprinted by H. C. Lea's Son & Co., Philadelphia, for the nominal price of ten cents. It is badly printed on poor paper, but has 77 pages, and is of course cheap for the money. But we regret to see a publishing house of this character going into that kind of business.

—The Sanitary Protection Association of Newport, R. I., is an excellent institution, the like of which ought to be organized in every city. This Association examines by its skilled inspectors into the condition of dwelling-houses and their surroundings, and advises concerning the plumbing, heating, ventilation, drainage and water-supply of residences already built or in process of construction. Also, the Association recommends to persons hiring houses or portions of houses, at any season of the year, to ask its certificate that the premises in question are in safe condition for residence. It makes the same recommendation regarding boarding-houses and hotels. Its members obtain all these benefits for only five dollars a year. It also publishes various health tracts, etc., the most recent of which is one on the dangers of impure ice, by Prof. Raphael Pumpelly. These and further particulars may be obtained of the Secretary, Dr. Horatio R. Storer, Newport, R. I.

—The annual address of Dr. Traill Green, of Easton, Penna., before the American Academy of Medicine at its last meeting, has been published in pamphlet form by the Academy, and will be found an interesting and instructive review of the origin and progress of the Academy.

—The National Temperance Society, New York, have republished an address by Dr. W. B. Carpenter on "The Physiology of Alcoholics." It assumes the ultra, teetotal position on the question, and is an able plea for absolute abstinence.

—In several papers published within the last few years, Dr. G. De Gorrequer Griffith considers that he has at last conclusively demonstrated that one poison—one *origo mali*, whatever it may be—will originate scarlet, typhoid and puerperal fevers, diphtheria, sore throats, erysipelas, diarrhoeal affections, and many other diseases, the character of the symptoms depending on the idiosyncrasy of the individual, his habits, surround-

ings, etc. Those who would study his arguments to this effect can probably obtain reprints of his papers by addressing the author, 34 St. George's Square, Belgravia, London.

—Under the title "What shall we do for the Drunkards?" Dr. Orpheus Everts, of Ohio, argues in a pamphlet before us that a prohibitory liquor law is impracticable and unwise, while an inhibitory law would be ample and protective. In other words, he would not enact a general sumptuary law because a few people become inebriates, but he would make it easy to segregate by force an inebriate from society. His arguments are timely, and they impress us as sound. (Pp. 51. Cincinnati, Robert Clarke & Co. Price, 50 cents.)

—Godey's *Lady's Book* now enters its fifty-third year, and its annual announcement holds out strong inducements to subscribers. It is an excellent family magazine.

—The value of Aiken, South Carolina, as a health resort during the winter months, is set forth in a neat little pamphlet, which may be had of Mr. B. P. Chatfield, Aiken, on application.

BOOK NOTICES.

Manual of Gynecology. By D. Berry Hart, M. D., and A. H. Barbour, M. A. Vol. I. New York, Wm. Wood & Co.

This volume is that for January of Wm. Wood's Library of Standard Medical Authors. It is more neatly printed and on better paper than its predecessors. The illustrations are moderately good and about two hundred in number. The text of the book is by two professors in that specialty in Edinburgh, pupils of Professor Simpson, and is written with that care and thoroughness—and also with those prejudices—which we expect from attachés of that famous and ancient university.

The Functions and Disorders of the Reproductive Organs. By William Acton, M. R. C. S. Sixth edition, Philadelphia. P. Blakiston, Son & Co., 1883. 1 vol., cloth, 8 vo., pp. 267. Price, \$2.

Mr. Acton has now been dead for some years, and we do not see that this treatise has been revised by any one since his demise. Hence, in many passages it is behind the age. Nevertheless, were we asked what better monograph exists on the subject, we could not name any. What especially distinguished Mr. Acton were his rare good sense and fine discretion in treating of subjects the most difficult of all to write about in the correct tone. In this respect his book is a model, and probably will long remain so.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D.,) EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, - - -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

IODOFORM IN DIPHTHERIA.

Diphtheria is a constitutional disease—this is not denied any more; but whether it is constitutional from its very beginning is not only very doubtful, but contrary to all sound reasoning. In case micrococci form really the pathogenic cause, they are first seen on the place of primary local affection, and from here they migrate and affect the blood in a similar, only more rapid, manner as the syphilitic virus. But granted that the disease is first purely local, and effective local treatment should be followed by such results as prove that the constitutional affection has been prevented by early destruction of the primary, local, exciting evil. Dr. J. Benzon in Buccari (*Wiener Med. Wochschrift*, 35-82), and Dr. S. Korach in Cologne (*Deutsch Med. Wochschrift*, 36-82) both have made experiments with the local treatment of diphtheria by iodoform. The former treated one man, two women, two girls, respectively aged 18 and 22, and a four-year-old child; and notwithstanding the cases were all of grave type, under the local treatment mentioned they all ran a very favorable and rapid course. B. treated his cases as follows: He took a painter's brush, 1 ctm. wide, and dipped it into finely-powdered iodoform till the points were all colored yellow. He then depressed the back of the tongue and applied the iodoform with the brush to the diphtheritic membranes. This procedure was repeated by B. in the beginning of the disease every two hours, about eight times during the day and six times during the night. With the exception of ice application to the neck, this formed the whole treatment.

He made use of this treatment under and by direction of Prof. Leichtenstern, the physician-in-chief of the Cologne City Hospital. For nearly a year all the patients in this institution suffering from diphtheria were treated with iodoform alone; cleansing injections with unmedicated water being the only local or internal medication used besides. First, iodoform triturated with amylum, was insufflated; then the dried powder alone was put by a brush upon the membranes. Later these methods were dropped, and instead of them iodo-

form with collodium (1 : 10) brushed six times daily over the diphtheritic exudations, the latter having each time been previously totally dried with a linen rag. Sometimes a solution of 2.5 in 25.0 sulph-ether, and 5.0 Tolu balsam, was made use of. The splendid results gained—of 213 cases only one death by laryngeal diphtheria—should induce far more extensive trials with this drug.

MUTUAL AUTOPSY SOCIETY.

M. Gambetta, the great French statesman, belonged to the "Société d'Autopsie Mutuelle," the members of which direct that a scientific examination of their brains shall be made after death.

The wisdom which caused him to become a member of this association is not by any means the least evidence of his transcendent greatness. It requires an intellectual power of more than ordinary magnitude to enable a man to so rise above his surrounding influences as to be capable of looking down with indifference upon the foolish sentimentalities and the ridiculous display of morbid feeling about ourselves after death, which is so characteristic of and so strongly imbued in the average man. Recognizing that every dead body scientifically examined throws so much additional light upon science, and tends to explain still further the mysterious phenomena of life, of health and disease, and by so doing aids materially the physician in his healing ministrations, these great minds cheerfully and eagerly will their bodies to the scientific scalpel.

But we should go further than did Gambetta. Not alone the brain should be donated for scientific investigation, but every organ as well. The viscera may all be enucleated without rendering the body unsightly when prepared for burial. If the family physician, who had known and recorded the various ailments from which the body had suffered during life, was to compare notes with the pathologist who examined the organs after death, symptomatology would receive a great boost. Let us have a *Mutual Autopsy Society*; it must emanate from physicians, who realize its value; therefore let us set the example.

THE SALE OF POISONS.

Every now and again we hear of some poor unfortunate, who, tired and weary of battling with the world, seeks relief in self-destruction.

Laudanum, morphia, strychnia, prussic acid, or some equally dangerous drug, has been the means of carrying into execution this morbid determination.

Now then, where are these drugs procured? From some druggist, of course. On physician's prescription? In the majority of instances, no!

We have in every city a limited number of dispensing drug stores, in which it is utterly impossible to procure any poisonous drug save on the written prescription of a known physician. But on the other hand, we have also many stores into which any one may go and buy an ounce or so of laudanum, without let, hindrance or question.

That such is wrong, we all know; let us stop it—how? By new legislation or by the enforcement of existent legislation, imposing an exceedingly heavy fine upon any druggist selling any poisonous drug to any person without a physician's prescription for the same. Compel all druggists to place their names upon every box and bottle that leaves their stores, thus giving a clue by which offenders may be traced. Of course it may happen that the name attached to the prescription is unknown to the druggist; he should then make inquiry, satisfy himself thoroughly in some way that the physician is all right. We ourselves, one time, in a neighboring State, had occasion to prescribe a dangerous drug; we were totally unknown to the druggist, but the character of the family to which our patient belonged was a guarantee of our respectability.

We cannot prevent men from shooting themselves, or from jumping over Niagara, or from drowning in lonely rivers; but we can, to a great extent, prevent this wanton waste of life from poisonous drugs, and it is the imperative duty of every one of us to look to it that we leave no effort untried to strictly limit the traffic in deadly drugs to its ordained and legitimate channels.

COMMISSIONS TO PHYSICIANS.

More than once in this journal we have pointed out why commissions paid to physicians, either by druggists or proprietors of sanitariums, private hospitals, or other health resorts, are against sound ethics, and in the end debasing to the profession.

Before us lies a circular sent out broadcast to the profession by a physician who runs a sanitarium in this State. The circular contains this "confidential offer :—"

"For each and every paying patient which you send to this sanitarium, we will remit you two dollars in cash per week as long as your patient remains," etc.

We ask any one of our readers whether he would like his patients to know when he sends them to such a place that he receives about 20 per cent. of their board bills as his share?

If he would not like them to know of it, let him ask himself, why not?

He must honestly answer that he would be ashamed of the fact. He would consider himself lowered in their estimation. In other words, he knows he would be doing a mean thing.

Is not this reason enough for condemning any such offer, and for rebuking the man who extends it as a bait to his professional brethren?

Again, it is the duty of the physician when asked by his patient to recommend a health resort, to select one without being at all influenced by his personal interests. Unless his choice is entirely unbiased, it is dishonest. Now, even the sum of two dollars a week has its attractions, and will obscure the judgment to a certain extent. Hence any such offer is a direct incentive to dishonest advice.

All this business of commissions, and discounts, and sharing in profits derived from treating the sick, is lowering to the tone of the profession. Such practices belong to trade, where they are expected and customary, and where they do no hurt. They cannot be introduced into professional relations without direct injury to the public.

It were sound advice for all physicians to take to repudiate every such offer, and to decline to

send any patients to institutions which show such a lack of moral sense as to make them.

RELIGION OF DARWIN.

During the meeting of German natural scientists and physicians, held last year in Eisenach, Prof. Ernst Haeckel lectured on the natural religion of Darwin, Goethe and Lamarck. In the course of this lecture he made the following remarks :

"That Darwin also adhered to the same natural religion as Goethe, and that he was no adherent of any special church-confession, is apparent to any one reading carefully his works. But as some of his countrypeople have immediately after his death contended the contrary, and as some bigoted ministers have praised Darwin as an orthodox adherent of a special confession of the English church, we will be permitted to contradict them by the following undeniable proof. I am so fortunate as to be able to introduce here an exceedingly valuable, so far unknown document, which will remove every doubt that might possibly exist.

"A young German student, whose Christian religion had been shaken by the perusal of Darwin's work, and who had entered the intermediate stage of doubt, wrote to Darwin, for the purpose of getting the advice of this eminent natural philosopher. At first one of the relatives of Darwin answered by excusing the latter's ill-health, great age, and want of time, which prevented him from deciding the questions put to him; but the German student was not satisfied, and so he once more, driven to it by his anxious doubts, wrote to Darwin, begging him to help him in his dilemma. He then received the following letter, written and signed by Darwin himself :

"Down, June 5, 1879.

"*Dear Sir* :—I am very busy, an old man and in bad health, and I cannot gain the time to perfectly answer your questions, supposing that they may be so answered. Science has nothing to do with *Christ*, excepting in so far as the habit of scientific exploration makes a man cautious in recognizing proofs. As far as concerns myself, I do not believe that there has ever taken place any revelation. But regarding a future life, everybody has to decide for himself between contradicting uncertain probabilities.

"Wishing you future welfare, I remain, dear sir,

"Very respectfully yours,

"CHARLES DARWIN."

NOTES AND COMMENTS.

Hardening Plaster Casts.

Thos. Fletcher in the *English Mechanic* says, "that plaster casts or moulds can be hardened by boiling them for half an hour in a strong solution of potash alum." Another and more convenient way is to paint the plaster cast after it has become thoroughly dry with ordinary shellac varnish, repeating the coats until the plaster will not absorb any more of the varnish.

A New Evacuator.

The simplified evacuator for litholapaxy of Henry J. Bigelow, M. D., described in the *Boston Medical and Surgical Journal*, is indeed an ingenious and useful instrument that is a great improvement upon those formerly used by Sir Henry Thompson and others. The principal defect in these evacuators is that they all allowed the return of a few fragments of stone after they had been washed out, and in this way the surgeon furnished a nucleus for the formation of the very evil he was working so faithfully to root out. A minute description of Dr. Bigelow's improvement cannot be given here, but he overcomes the difficulty by prolonging the catheter into the bulb of the evacuator, which prolongation may have a valve at the end, and whose sides are perforated. The fragments of stone are easily washed by the current through the trap end into the bulb. When the bulb is compressed, the water readily finds an exit through the perforations, but no fragments can pass through. The instrument possesses still another advantage in being easily taken apart and cleaned when clogged by mucus and other matter.

Sympathetic Ophthalmia Following Extraction of Cataract.

From the *Dublin Journal of Medical Science* for December we note that Mr. W. J. Milles, House Surgeon to the Royal London Ophthalmic Hospital, relates eleven cases of "undoubted sympathetic inflammation" following extraction of cataract, and due to that cause. He states that one of his "reasons for giving an account of these cases is that often more may be learned from the disasters than from the successes of surgery." "All the cases were fairly good subjects for operation; the cataracts were not complicated by any other disease of the eyes; the pupils were active, projection good, tension normal." The interval between the extraction and the onset of sympathetic

ophthalmitis was, as a rule, two to three months. The shortest period was six weeks, the longest fifteen months. In the sympathizing eyes the tension varied from time to time; one day it would be normal, another day increased. This variation in the degree of tension is, he believes, one of the characteristics of sympathetic inflammation.

Sulphur as a Disinfectant.

M. d'Abadie recently read a paper before the Paris Academy of Medicine on "Marsh Fevers," in the course of which he made a strong plea for the properties of this rather neglected disinfectant. He cited many illustrations in favor of his argument, among others, that in the dangerous regions of African river mouths immunity from such fever is often secured by sulphur fumigations on the naked body. Also that the Sicilian workers in low ground sulphur mines suffer much less than the rest of the surrounding population from intermittent fevers. M. Fouque has shown that Zephyria (on the volcanic island of Milo or Melos, the most westerly of the Cyclades), which had a population of 40,000 when it was the centre of sulphur-mining operations, became nearly depopulated by marsh fever when the sulphur-mining was moved farther east, and the emanations prevented by a mountain from reaching the town. A simple way to use this article is to drop a quantity of flowers of sulphur on a red-hot stove.

Orbital Cellulitis.

Orbital cellulitis, as a sequel to facial erysipelas, is ably dealt with by Prof. Williams in the *Boston Medical and Surgical Journal*. It cannot be said that this lesion usually follows an attack of facial erysipelas, but any case is liable to it, and should its cause and treatment be misunderstood by the physician, fatal consequences may result. It begins with a full and tense feeling in the eye—the pain, at first dull, soon becoming more intense; the eye protrudes; vision, primarily not affected, suddenly fails. The ophthalmoscope shows little change in the disc, except that the retinal vessels are much smaller than usual, owing to pressure of inflamed tissues upon vessels of the orbit. The treatment must be prompt and decisive, or irreparable damage may ensue from pressure upon the optic nerve and blood-vessels; besides, the protrusion of the eye-ball beyond the lids is likely to be followed by ulceration of the cornea. Septic matter conveyed by the ophthalmic veins may cause pyæmic abscesses or heart-clot. The treatment

consists in introducing a bistoury or Graefe knife between the eye and orbit at that point nearest which the abscess seems to be forming. The back of the blade should enter next the eye-ball and the point pass well back to the fundus of the orbit. Even if pus has not formed, the tension will be relieved by the escape of blood. This treatment, though it does not always save the vision, gives speedy relief to other symptoms, and the patient usually makes a rapid recovery.

Physiology of the Cerebrum.

Since Hitzig, Ferrier and others started their experiments to determine the localization of the functions of the brain, hundreds of industrious investigators have continued their labor in the same direction. The latest of this kind we see in Pflüger's *Arch.* xxviii., p. 579, where Fr. Goltz publishes the results of his experiments on dogs. He found that these animals, if both temporal lobes are extensively and deeply destroyed in them, not only show diminished intelligence, but that also their character, if we may use this word, or their very nature, becomes profoundly altered. Harmless and good-natured animals become after this lesion very irritable; bad-humored show inclination to fight and bite even their masters. But in case the destruction affects the posterior lobes of the cerebrum only, the animals not only continue their harmless and good-natured character, but seem to become milder still, while their intelligence is, if anything, still more affected. We may conclude from this, that the temporal lobes seem to exert a kind of inhibiting influence on the animal passions, and that the latter are instigated in the posterior lobes, which again, as far as intelligence is concerned, seem to be in intimate connection with the anterior lobes.

Poisoning by Gelsemium Sempervirens.

In the *Medical Times* for December 30, 1882, Dr. L. L. Friedrich, of Washington, D. C., reports an interesting case of poisoning by gelsemium sempervirens, in which a teaspoonful of an old fluid extract was taken by a girl 14 years of age by mistake for bitter wine of iron. The first symptoms manifested themselves forty-five minutes after ingestion of the poison, viz., dizziness, headache, muscular relaxation, and slight convulsive movements. Improvement took place under a hypodermic injection of one-eighth of a grain of morphia. Soon after, however, the untoward symptoms returned with increased severity. Excessive muscular relaxation and incoordination manifested themselves. The pupils were dilated,

diplopia, ptosis, paralysis of the facial muscles and excessive salivation were present. The face became congested, the tongue "thick," and deglutition well nigh impossible, together with other symptoms, resembling hydrophobia. Finally, the patient passed into a semi-comatose condition and the symptoms of collapse supervened, until the girl was totally unconscious, with a feeble, thready pulse, gasping respiration, cold, clammy skin, and failure of circulation in the extremities. A judicious treatment by emetics, cardiac and respiratory stimulants and artificial respiration was instituted, with the gratifying result of restoring the patient to health. No sequelæ are noted, except weakness and dizziness. The original improvement which was noted under the use of morphia is interesting as being confirmatory of an observation made by Dr. G. S. Courtright (*Cincinnati Lancet and Observer*, 1876, p. 963), that morphia was antagonistic to gelsemium, detailing a case in which recovery took place after the ingestion of two teaspoonfuls of the tincture, the treatment having been hypodermic injections of morphia.

Contagion of Leprosy.

The question of contagion in leprosy was the subject of controversy before the American Dermatological Association, in August, 1882. One case occurring in Louisiana, was that of a Catholic priest, who was ministering to a family of lepers. He contracted the disease, and died in a short time. In sixteen years, only two cases have been observed in the State of New York. One of these had associated with lepers in Mexico, the other had never been out of the State. A case was reported before the Philadelphia Pathological Society in November, 1882. The larynx and also a cast of the hands was exhibited. The patient was originally from Cuba, and contracted the disease there. Leprosy is not supposed to be communicated in the ordinary way, that is by atmospheric influence or ordinary intercourse, but more like syphilis, requiring the blood or secretions to come in contact with a healthy person. The disease is thought by some to be an outgrowth from syphilis. The period of incubation varies from one to sixteen years. Inoculation is admitted to be the principal method of communication. In 1843, a child was inoculated by being vaccinated with matter from a leper. Subsequently it came to this country and died at the Bellevue Hospital. Leprosy is due to the bacillus lepræ, which have been found by a number of noted gentlemen in the profession, such as Koch, Cornil, Schmidt, and others.

Effect of Potash and Sodium Salts on the Muscular Tissue of the Bowels.

From several notices published in the MEDICAL AND SURGICAL REPORTER, our readers will have learned the results of investigations recently made by Nothnagel for the purpose of determining the mode by which potash and sodium salts cause purgation. Prof. Bardeleben has taken up the same subject (*Virchow's Archiv.*, lxxxix., p. 190). He found in the intestines of a murderer, who had been decapitated, that when touching them with potash-salts, a few seconds later a depression was induced at the place of contact; later a transverse strangulation, which gradually spreads itself in ring-form all around the intestine. At the same time motion is noticed to be increased above and below the place, for a distance of about 10 ctm. The same observation had been made by Nothnagel, but what he was not able to determine, Bardeleben succeeded in establishing, viz.: That the same results were achieved also with sodium salts, only in a less degree. B. agrees with N., that the phenomena caused by sodium salts cannot be ascribed to direct muscular, but to nervous irritation, and he believes that in the intestines such contractions are easier shown in the long- and ring-muscles, as they can be seen better and run separate from each other.

Influence of Electric Light on Health.

The influence of the electric light on health was lately discussed at a meeting of the Hygienic Society of Hamburg, and Dr. Kruss gave his views on the subject at some length. He referred to the influence of the electric light on the human eyesight, and expressed his opinion that it produces no evil effects, the light having a violet tinge under most circumstances. The electric light being free from the disadvantages incidental to the combustion of gas, in the consumption of oxygen and the production of carbonic acid, he considered its development as being a hygienic measure of importance.

Intermittent Spinal Paralysis.

Generally speaking, malaria causes far more frequently affections of other parts of the human organism than such of the nervous system, if we except neuralgias. That, however, sometimes the nervous centres suffer severely, and especially the spinal cord, has also been attested to by many cases on record. Very interesting is the following case which Dr. V. O. Gibney publishes in the *Jour. of Neurol. and Psych.*, 1882, 4. Five times a boy, 7 years old, was attacked by diffuse paralysis

due to malaria, and especially of the lower extremities. Each time an energetic treatment with quinine and removal out of the affected locality induced a cure. The electric excitability of the emaciated and paralyzed muscles was greatly diminished; typical reaction of degeneration was, however, wanting. In a second case, a boy æt. 6, had twice similar seizures. Dr. Gibney supposes that congestion of the spinal marrow, first active and later passive, hyperæmia accompanied by oedema, form the pathological-anatomical basis for these paralyses. The cord surely is not affected organically, otherwise the cure due to quinine would not be so effective and radical.

CORRESPONDENCE.

A Question in Pathology.

EDS. MED. AND SURG. REPORTER:—

About a dozen physicians met on the 9th ulto. to hold a post-mortem examination on the body of the late Mr. B., in order to determine whether he had been suffering from structural disease of the heart, or Bright's disease of the kidneys. The first thing apparent was extensive pericarditis, which had resulted in considerable adhesion of the pericardium to the walls of the heart. The organ was somewhat enlarged from the normal standard, weighing 18 ozs., the normal weight being from 10 to 12 ozs., or in proportion to the weight of the body as 1 to 169. According to this the hypertrophy would be very slight, as Mr. B. was a man weighing some over 200 pounds. There was no evidence of endocarditis, as the cavities of the heart presented nothing abnormal more than a slight calcareous deposit about the mitral valves. The valves were not enlarged at all, there were no red or ulcerated spots, nothing save this slight deposit which consisted of several small incrustations on the walls of the auricle and one on the valves. By passing the finger through the valves one could detect the bony projections.

The kidneys were imbedded in adipose tissue; and were examined and measured after the capsule had been removed, which took with it small particles of the substance of the kidneys as it was peeled off. The size was very nearly the normal standard, but slightly diminished. The surface of both kidneys after the removal of the capsules was rough and studded with numerous small and rounded elevations, with several cysts on both kidneys.

It was therefore apparent to all that in case of the heart there were pericarditis, a calcareous deposit above the valves of the left ventricle, and also an hypertrophy of the left ventricle. It was also apparent that the kidneys were slightly contracted and granular, which is one of the forms of Bright's disease of the kidney. Therefore the question was raised as to which was the primary disease. This question raises another, viz., will either disease produce the other, and do statistics show that one is concomitant to the other? It is

stated in Cornil and Ranvier's Pathological Histology, page 626, where speaking of the contracting granular kidney, that "the surface of the kidney stripped of its capsule presents slightly prominent, sharply raised small granulations, the size of millet seed." On the kidneys under examination these granulations were so plainly marked as to be pathognomonic of that form of Bright's disease of the kidney.

In the January number of Wood's "Library of Medical Authors," Dr. Dickinson says (page 94): "In kidneys which have acquired granular surfaces, there has invariably taken place a certain definite change in the fibrous tissues by which the tubes are separated. Of this the alteration of the surface is at once the result and the proof." On page 95, Dr. D. also states that "Granular degeneration begins in a slow and insidious manner, the departure from health being most gradual and indefinite." The fact cannot therefore be denied that when we get the granular kidney we have the incontrovertible evidence of a long-standing disease. Prof. Da Costa, in his work on "Diagnosis," page 698, says it may exist for years unsuspected, and that there is tendency toward convulsions, coma, hypertrophy of the left ventricle, and cysts of the kidney. In Flint's "Practice of Medicine" the professor says, "One of the most constant accompaniments of the small granular kidney is the hypertrophy of the left ventricle. There may be hypertrophy of the whole heart." He also speaks of the increase of adipose tissue around the kidney, which was decidedly marked in the case of Mr. B.; and Prof. Flint states on page 884 of his last work that "pericarditis is secondary, especially to the granular kidney," and that vomiting and delirium are common symptoms of this disease. In Reynold's "System of Medicine," vol. ii., page 591, it is shown that in one-half of 259 cases of Bright's disease of the kidneys there was hypertrophy of the left ventricle. There is abundant proof by this author to show that every heart complication that was found in the autopsy of Mr. B. is a common result of Bright's disease of the kidney, especially of the granular form; but whether it be granular or fatty, acute or chronic form, the action of the left ventricle is always unduly strong, and the tendency towards hypertrophy is great.

I could quote authority and give statistics to almost any extent to prove that the heart lesions as found at the autopsy are often the direct result of the granular kidney; and when we remember that the granulations found upon the kidneys of Mr. B. are *prima facie* evidence of a long-standing renal disease, and also when we recall to mind the fact of the itching and the vomiting, the delirium and the convulsions, the heart complications and coma, that were present with Mr. B. during the last of his illness, all of which point directly to Bright's disease, we can come to no other conclusion than that the granular kidney of Bright's disease was the primary trouble of this patient, and that the heart lesions were concomitant.

OBSERVER.

[The gentleman who forwards the above description desires our opinion as to the justness of his conclusion. Of course, we can speak from the record only. As it stands, we should think his position is the correct one.—Eds. REPORTER.]

Hives.

EDS. MED. AND SURG. REPORTER:—

The "information concerning 'Hives'" asked for by your correspondent, Dr. J. E. F., will vary greatly in its character and value, as it may be the result of observation confined to the surface of the body; or, contemplates its deeper springs in the vitiation of the physiological processes of the animal economy. He who is most successful in detecting the occult origin of nerve irritation, will be likely to throw the most light on the source of obscure affections, and to relegate to their proper place those phenomena which, being only symptoms, are ranked as diseases. My experience being in the lighter and less recondite cases, may be useful only as a suggestion as to the cause of the manifestations, which, once ascertained beyond question, puts one upon the high-road to their cure by sapping the fountain.

Early in my practice, I was sent for in the greatest haste to see Mrs. H., who was said to be "choking with the bold hives." A quick response to the call showed how urgent was the necessity for relief; the patient gasping in great excitement from constriction about the throat. Ascertaining that she had recently partaken of fish, an emetic was given, with prompt subsidence of the alarming symptoms.

In REPORTER, Vol. XLIII., p. 353, article "On Quinine in Fevers and Disorders accompanying Them," I related the following case, which is here reproduced for the sake of any who may not have seen it. "Mrs. H. W. S. has had a chill, followed by fever and severe pain in the region of the liver; the skin being elevated in wheals by urticaria. Laxative doses of calomel, with citrate of potash, were employed during the first two days of treatment, after which full doses of quinine were given, the symptoms all disappearing with the fever. Subsequent attacks of like character, in the late summer and autumn, were treated in the same way with good results." This lady, who had always been treated by her former attendant for "hives," would not at first believe that these manifestations, so named, were only the symptoms of another disease.

As in the case under observation, "dyspepsia or profound impression of the nervous system usually precedes the attack," it would appear that connected therewith lay the grounds of a reasonable etiology, and a rational and successful treatment. If we can remove the dyspepsia, which is also probably only a symptom, we shall at the same time get rid of the nervous trouble of which the "hives" are a part. The following case may be suggestive in this connection: A gentleman, whose stomach was so irritable as to be constantly rejecting food, and was the focus of all those varied discomforts denominated dyspepsia, was treated by remedies having direct application to this organ. When all means thus directed had failed, I was enabled, on taking charge of this case, to find the *fons et origo* of all the trouble in the liver; and to make a rapid cure by pil. hydrarg., seidlitz, and vegetable bitters.

A valuable hint may therefore be found as to the etiology and cure of "hives," as of many of the diseases of the human race, in the sage remark of Sylvius, in his "New Idea of the Prac-

tice of Physick" (London, 1675): "Man's health is manifested by the perfection of all his functions, and his sickness by the hurt and deficiency thereof."

E. T. BLACKWELL, M. D.

Paterson, N. J.

The Influence of Alcohol on Bright's Disease.

EDS. MED. AND SURG. REPORTER:—

In your issue of November 25, 1882, page 604, Dr. Meigs concludes his very valuable paper on "Albuminuria" with a sentence concerning the influence of alcohol on kidney disease. While one case proves nothing, I would like to present the following singular case, to say the least, to your readers:

A. W., age 33, is to-day a man weighing about 180 pounds, is strong, robust, and apparently as well as any man can be. Well, about eight years ago, feeling a little out of sorts, he consulted his physician and found he had kidney disease, there being both albumen and casts in the urine. A careful life was enjoined, which was followed for maybe six months, when he relapsed into his old habits, viz., the quite free use of whiskey and tobacco. He had been addicted to both of these habits since very early manhood. About three years ago he contracted a most terrible case of syphilis, suffering with enormous lupoid sores all over the body and the most profound constitutional symptoms for more than a year. During this time he drank and smoked harder than ever; in fact, so depressed was he by his misfortune that he did little else but loll about and keep all the time to a certain extent under alcoholic influence. Finally the sores healed and he commenced to improve; having been reduced to 120, he now, as I have said, weighs 180 pounds. While he drinks less than formerly, yet he now daily consumes at least ten to twelve ounces of whiskey. I should add that he has a sanguine temperament and the most remarkably *easy-going* disposition I have ever encountered, which may, perhaps, account for the mystery.

Ohio.

NEWS AND MISCELLANY.

Free Quinine.

The House, in Committee of the Whole, last week, struck from the Tariff Bill the item placing a duty of 10 per cent. on sulphate and salts of quinia, and cinchonidia.

The vote stood 108—57, and the result was received with applause on the Democratic side.

Why not go a step further, and put on the free list the articles essential to the manufacture of quinine, so as still further to cheapen this valuable remedy?

This is the point that we have repeatedly urged on those interested in this subject.

Nurses' Directories.

The nurse is the assistant of the physician, and a good nurse is often an indispensable assistant, if the patient is to have a chance of weathering the disease. Hence it is an admirable plan now

in vogue in Philadelphia and Boston to organize a bureau or directory, where nurses can register their names, addresses and engagements, and where physicians and the public can promptly secure their services.

That in Philadelphia is at the northeast corner of 13th and Locust streets, and is in charge of Miss Emily Thomas, Secretary of the Association, who has the matter in care. She can be communicated with by telegraph, and nurses can be promptly despatched to the country. Particulars as to fees and prices can be obtained by addressing her.

Habitual Drunkards' Act.

A bill has been favorably reported to the Senate of this State allowing habitual drunkards, by order of the Court, to be confined in inebriate asylums by their relatives for care and treatment.

Epidemics.

The Board of Aldermen of Providence, R. I., have ordered that all vessels from Baltimore shall be quarantined.

The reports of small-pox around Salem, Va., are said to be exaggerated.

The Wytheville (Va.) *Dispatch* says that the extent to which the scarlet fever is spreading throughout the Valley of Virginia is appalling. About a month ago it broke out near Staunton, and has since reached that city, and spread to such an extent that many of the schools have been forced to close.

Money for the Feeble-Minded.

Henry M. Diabert, of Philadelphia; Evan Rogers, West Chester; and Dr. Isaac N. Kerlin, Superintendent of the Pennsylvania Training School for Feeble-minded Children, at Media, were before the House Committee on Appropriations at Harrisburg recently, asking an appropriation of \$40,000 for the maintenance of that institution, and \$30,000 to finish and furnish the building.

A Compliment to American Medical Journalism.

The *Medical Times and Gazette* says: "The surprising familiarity shown by American physicians with the latest researches in this country and on the Continent is, we fear, scarcely enough reciprocated by us." This familiarity is owing chiefly to the enterprise of our medical journals.

Calhoun County (Mich.) Medical Society.

At the recent meeting of this society the following officers were elected for the ensuing year: President, Dr. M. W. Tomlinson, of Battle Creek; for 1st Vice-President, Dr. Joy, of Marshall; for 2d Vice-President, Dr. Alvord, of Battle Creek; for Secretary and Treasurer, Dr. W. B. Sprague, of Battle Creek.

Female Brain Work.

From the *Medical Times and Gazette* we note the following: "Referring to much that had been said and written lately about the overworking of girls and young women in schools and colleges,

and that his friend Dr. Clauston had come forward as the champion of health and ignorance for women, Dr. Tuke thinks that Dr. Clauston had overstated the position of matters, that he had based his opinions more on the observation of isolated cases than on the general condition of highly educated women; that he had mistaken the wail of the one for the murmur of the many. No doubt a certain number of young women suffered and broke down whilst studying, but this did not necessarily imply that study was the cause of the breakdown. Idleness and ignorance were much more prolific causes of disease amongst women than overwork. They were the main producers of hysteria and all sorts of vapourish complaints, of many ills and evils, and of insanity, if not of insanity. As a matter of fact, it was not an easy thing to overtask the energies of the brain by work. It was not work, but worry, that killed the brain. The latter, he feared, must be ever with us all. The most highly educated and hard-working women whom he had the honor of knowing were eminently healthy. Perhaps this might be the 'survival of the fittest'; but, even granting that it was so, the more women worked the more fit women they would have. The breakdown from overstrain did occasionally take place, and the first really important symptom was sleeplessness; when that set in, there was cause for alarm. As soon as a child or young person developed continuous headache, work should be discontinued."

These are sound doctrines and deserve extensive notoriety.

Baby Farming in France.

The French act, passed in 1874, for the protection of children of tender age placed under care of "baby farmers" (a numerous class in France), and other persons, who, for a consideration, undertake the charge of one young child (likewise a large class), has worked sluggishly. The funds allotted for the purpose have been insufficient, and the work has been indifferently seconded by the local boards. But ministers have by degrees improved the service, by additional remuneration to different functionaries already existing, and good results are expected.

Expensive Quinine.

During our war and for a long time afterwards, perhaps still to-day, there has been a widespread rumor that persons who had been entrusted with delivery of articles necessary for the army by contract, had become remarkably rich by charging exorbitant prices. We read in an editorial of the "Wratsch" (Russian medical paper, *The Physician*), that a suit has been instituted in Petersburg against Counsellor Koslow, former chief of the "Sanitary Bureau" during the Turko-Russian War. The main object is to find out, if there was anything "crooked" in the delivery of quinine for the army, which was totally in charge of Koslow. Before the war a pound of quinine was sold for 42 rubles (1 ruble about 80 cents); it became dearer during the war, but Mr. Koslow charged the government from 100 to 208 rubles—nearly 160 dollars per pound of quinine. They seem to understand money-making, not in America only, but even in Russia.

New York State Medical Society.

We have received early reports of this meeting, and in our next issue will furnish a full report. The resolution to repeal all action taken at the meeting in 1882 in regard to changing the Code of Ethics, offered by Dr. Squibb, of Brooklyn, was debated long and fiercely, and finally defeated by a vote of 105 to 99. This leaves the new code in force, and still further alienates this Society from the profession at large.

The Physician's Chance for Saving.

Dr. Cotting, in the *Boston Medical and Surgical Journal*, says that it may reasonably be doubted whether even in the city, where the fees are nominally the largest, the average income of the profession allows a greater margin for savings than that of the laborer who sweeps the streets or carries the garbage.

Personals.

—A portrait of Oliver Wendell Holmes by Alexander, of New York, to be presented by his former pupils to the Harvard Medical School, has been on exhibition in Boston.

—Dr. E. Fletcher Ingals has been made Professor of Laryngology in Rush Medical College, Chicago.

—Dr. Joseph T. Smith has resigned the Chair of Anatomy in the Baltimore Medical College. Dr. Thomas Dougherty has been appointed Lecturer on Physiology in the same institution, *vice* Dr. B. F. Leonard, resigned.

—Mrs. Elizabeth A. Beard, wife of the late Dr. George M. Beard, died of pneumonia at the Grand Hotel, New York, January 31st. Only a few days before, her husband died of the same disease.

—Mr. Lawson Tait has been elected an honorary member of the American Gynaecological Society.

Items.

—In Portland, Maine, where they have a stringent liquor law, the percentage of arrests for drunkenness to the population was, in 1880, 3.56; in New York it was 2.44.

—The continued increase of mortality in St. Petersburg—arising from zymotic diseases—is creating considerable alarm. The municipality has expended 50,000 roubles in sanitary measures, but nothing practically effective against the ever-growing death-rate has been devised.

—A resurrectionist in Washington was recently sentenced to an imprisonment of eleven months and twenty-nine days.

—The Spanish Government has received a telegram dated December 28th, from their Consul at Suez, announcing that cholera has appeared amongst the pilgrims from Mecca and Medina, and that the deaths from the disease at the latter place number ten daily.

—The Académie des Sciences at its last meeting appointed a committee, with M. Milne-Edwards as its president, to co-operate with the English committee for raising a memorial to Charles Darwin.

—Dr. Charles F. Moore reports a case presenting neuralgic symptoms in a man having remarkable patches of white hair, some of which were congenital.

—The New York *Tribune* publishes some statistics of suicides in that city during the last twelve years. In that period 1,687 persons took their own lives; 1,326 were men, and 361 women.

—The proof of numerous inhumations before life was entirely extinct has incited the Paris Academy of Sciences to award a prize of 2,500 francs to the author of the best work on the positive symptoms of death and on the most efficacious means of preventing premature burial.

—A boy of eight years died in England, poisoned by the action of a substance used in dyeing his stockings. Sir John Humphreys testified that several striking proofs had come under his notice of the danger of wearing many of the dyed stockings offered for sale.

—The *Shenpao*, a Chinese newspaper, gives an account of a man thirty-four years old, with thirty-two children—sixteen pairs of twins. The father is a poor farmer, and the children are supported by their neighbors. The *Shenpao* is silent as to the mother.

—The last alleged discovery is that there are horned men in Africa. A Captain J. S. Hay recently read a paper before the British Association in which he stated that he had seen them, and exhibited sketches of them. He thought they belonged to the class of malformations of which there was a noted example in the case of the "porcupine man," who had horny plates on various parts of his body.

—Dr. E. M. Snow, in his annual report as Registrar of Providence, R. I.,—a city of over 100,000 inhabitants—makes the striking statement that there was no case of small-pox in Providence during the year 1882, and the last death in the city from this disease was in July, 1875; indeed, there has been only one death from small-pox in Providence since May, 1873, nearly ten years.

OBITUARY NOTICES.

DR. J. PH. TRAU.

Dr. J. Ph. Trau, a well-known German physician, died at the residence of his son, Dr. Adam Trau, in this city, on Thursday morning, Feb. 1st, aged 73 years. His death was quite sudden; having just returned from his usual afternoon walk, he was prostrated at his doorstep with a stroke of paralysis, and died eight hours later. Dr. Trau was born in Germany, and graduated as a Doctor of Medicine in a Munich College. He took an active part in the German revolution of 1848, and to avoid possible arrest for his participation in that historical event, he left that country in 1850 and settled in this city, where he has since lived. He had a very large medical practice among the German population, but in 1871 he relinquished it to his son, Dr. Adam Trau. He was a member of several German societies, and an active Mason. He was also an organizer of several building associations directly after his arrival in this country. He leaves two sons.

LIEUTENANT-COLONEL CHARLES C. KEENEY, U. S. A.

Dr. Charles C. Keeney, who died January 30, was a native of New York, but was appointed from Michigan as Assistant Surgeon of the United States Army, July, 1842. He served with the Army of Invasion in Mexico in 1848, afterwards being stationed at different points in the South and West until the breaking out of the Rebellion, when he joined the Army of the Potomac as Inspector of Hospitals. In October, 1865, having been breveted Lieutenant-Colonel for services during the war, Keeney was made Post Surgeon at San Francisco, and permanently stationed at that point. In June, 1876, he reached the rank of Lieutenant-Colonel.

DR. GEORGE M. BEARD.

Dr. George M. Beard, of New York city, who had made a considerable reputation by his numerous writings on diseases of the nervous system, and who was prominently identified with the Guiteau trial, died in New York on January 23.

QUERIES AND REPLIES.

EDS. MED. AND SURG. REPORTER: In reply to the interrogatory of "J. E. F., M. D.," I will say that the remedy for "hives" is hot whiskey punch, given at short intervals, until the patient begins to feel the intoxicating effects of the alcohol. Frequently, one strong drink of toddy is quite sufficient to arrest an attack and allay the terrible itching and burning sensations of hives; and in chronic cases, an ounce or two of whiskey or gin, given immediately after each meal, soon remedies the morbid irritability of the nervous system said to be the cause of hives. The next best remedy in chronic cases is, sulph. quinine grs. ij, pulv. capsicum grs. iij, sulph. ferri gr. j, pulv. aloes gr. ss, made into three pills and taken three times a day after each meal. If the tongue is coated, an occasional mercurial purge is always beneficial. As a local application, hyposulphite of soda one drachm, carbolic acid, grains twenty, one drachm of glycerine and seven drachms of water, make the best wash for the itching and burning.

J. B. JOHNSON, M. D.

Washington City, D. C.

MARRIAGES.

HARRY—LONGAKER.—At the residence of the bride, in Norristown, by the Rev. A. J. Weddell, on the 31st of January, Dr. C. Howard Harry and Miss Lizzie Longaker, both of Norristown, Pa.

HIETT—DEARMAN.—At the 6th Presbyterian church, on Thursday evening, December 28, 1882, by the Rev. H. T. McClelland and Rev. E. P. Cowan, D. D., Dr. G. W. Hiett and Mrs. M. DeArman, all of Pittsburgh.

RAYNES—DAVIS.—At Lebanon, N. H., January 17, by the Rev. M. V. B. Knox, D. D., assisted by Rev. J. M. Dutton, John B. Raynes, M. D., of Bradford, N. H., formerly of Lebanon and Emma A. Davis, of Lebanon.

VAN FLEET—OAKLEY.—On Wednesday, January 31, 1883, at the residence of the bride's parents, Frank Van Fleet, M. D., of New York city, and Carrie B. Oakley, of Orange, N. J.

RHOADS—DAWKINS.—At the residence of the bride's father, in Dallas, Texas, January 17, 1883, by the Rev. Mr. Moore, H. H. Rhoads, M. D., of Aubrey, Texas, and Miss M. P. Dawkins.

DEATH.

SEEGAR.—At his home, in Fairmount, Ohio, January 22, 1883, Dr. Jabez Seegar, aged 77 years.

THE STANDARD PREPARATION OF IRON.

SOLUTION FERROUS MALATE.

(4 Grains to fluid drachm.)

A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not constipate, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Cinchona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts.,

CLINICAL STUDIES OF INEBRIETY.

TREATMENT BY LEGAL MEANS.

BY T. D. CROTHERS, M. D.,

Supt. of Walnut Lodge, Hartford, Conn.

The State of Massachusetts, in 1879, punished by fines and imprisonment seventeen thousand five hundred and seventy inebriates. Of this number, three thousand four hundred and fifty were convicted of various crimes against persons and property. The punishment inflicted varied from five days' to sixteen years' imprisonment; and the fines imposed ranged from one cent to one hundred dollars. Of the three thousand four hundred and fifty who were convicted of crimes, two thousand and ninety-seven were intoxicated at the time of the commission of the crime, or literally suffering from the toxic action of alcohol, in which the brain is influenced by all forms of delusion, hallucination, and delirium, being therefore in an unsound state of mind. The control of the organism by the brain centres is lost, and diseased impulse takes the place of reason; hence, the want of responsibility for consequences of bad acts. If the three thousand four hundred and fifty sentenced for crime were literal criminals, and inebriety only a complication, the remainder punished were fourteen thousand one hundred and twenty inebriates suffering from no other affection.

These were inebriates, and the State, to care for and prevent any farther extension of the disorder, sends them to jail, or levies from them a certain

sum of money under the name of fines. This is based on the theory that inebriety is a vicious element under the control of the patient at all times: a disposition to sin which he makes no effort to check, but from which punishment in jails and loss by fines will enable him to hold this vice in abeyance. Wounding his pride and arousing a sense of fear and alarm, are supposed to act in breaking up all desire for drink. It is assumed by the State that the influences of society and friends are powerless, and that love and persuasion must give way to the strong arm of the law, which will, by force, bring about what is impossible by other means. Thus Massachusetts in one year fined and imprisoned over fourteen thousand inebriates, in the hope of curing and lessening inebriety.

In New York State, in one year, over fifty thousand convictions for inebriety are recorded, and so on in like proportion in all cities and states in the Union. This is evident in the results. Inebriety, pauperism, insanity, and the criminal classes, are steadily increasing. The number of commitments for inebriety is also increasing. The demand for jails, almshouses, and insane hospitals is greater now than ever before. Such institutions are crowded. This fact is startling, coming from the statistics of every jail and prison, that from ninety-eight to one hundred per cent. of all commitments for inebriety the first time, return under similar commitments and become repeated until sent either to insane hospitals, or to die in almshouses.

The New York State Board of Charities, from an examination of the inmates of the almshouses of

the State, found that from the vicious management of these institutions, there were influences which made more paupers than all the other conditions combined. Also, that the State's efforts to control or check pauperism were actually developing this class, and making them more and more incurable.

The same thing is true in the treatment of inebriety by legal means. The State of Massachusetts, with all her intelligence, is every year actually building up insanity, pauperism, criminality, and conditions of incurability, from the commitment and punishment of this vast army of inebriates. If these fourteen thousand inebriates were committed for the first time in Massachusetts, the lowest statistics indicate that ninety-six per cent. would be returned for the same offense over and over again, developing into an army of incurables that are a burden to society and State. Confinement in jails or prisons removes the inebriate from alcohol, but places him in surroundings of physical and mental degeneration from which recovery rarely follows. This is upon the same principle as removal of typhoid cases to small-pox hospitals, or treating insanity by sending patients to the hall of the stock board in Wall street, New York. Every case of inebriety is suffering from a low form of nerve debility and general impairment of all the organic functions. The brain is starved from defective nutrition, alcohol has broken up the healthy action of the nerve centres, and conditions of profound degeneration of both mind and body are present. The treatment by the State may be summarized as follows:

1. In jails and prisons, the nutrition is defective, and though the food is abundant, it is poor in quality and variety, and not being adapted to diseased persons, cannot build up healthy brain or nerve tissue. Prison diet always leaves a low state of nutrition, and opens the door for many diseases.

2. The ventilation is always wanting, and the absence of open air, proper exercise, sunlight, etc., all lower the tone and vigor of the organism.

3. The depressing influence of confinement in narrow, dark rooms, and surroundings that repel every instinct of faith and hope, destroys the central factor upon which recovery depends. The physical influence from the wounded pride merging into despair, and the enforced association with the lowest grades of humanity, leaves an impression more or less permanent.

In jails where inebriates are confined for short terms, the inmates are allowed free intercourse.

The results from this contact, are familiarity with the most degrading influences and the sympathy of a class that are outlaws to all that is good and true. In the penal methods of treating inebriates, not a single redeeming feature appears, except the withdrawal of alcoholic spirits. Every other appliance to build up and strengthen the patient to be well and temperate, is wanting. All medical means, all physical influences, and all help from surroundings and conditions, being wanting, they are replaced by the worst possible combinations of exciting and predisposing causes, forming a low chronic state that is incurable.

Of all methods (leaving out the disputed questions) the punishment of inebriates in jails is the most inhuman and unscientific, the effects of which are neither penal, educational, medical, hygienic, moral, nor economic. Hence, every inebriate who serves a term of imprisonment is removed farther from the possibility of recovery.

From the economic standpoint, the penal treatment of inebriates is a most extravagant and vicious system of legislation.

The true remedy is this: Build special work-houses, hospitals, remote from large cities and towns; the revenue to be obtained from the license fund. Then, when a man is declared to be an habitual inebriate, send him to these places, as the insane are sent to asylums. Make restraint from alcohol absolute; and furnish him work that will be a source of revenue to the institution and himself. Have in such places all the means to meet the varied complex symptoms of his case.

All appliances of science, church and state, should be used, which shall build up a healthy body and mind, and keep the inebriate from being a burden to his friends or the State.

This can be done with more ease and certainty than the Albany Penitentiary, which makes thirty or forty thousand dollars yearly above expenses from about one thousand inmates of the worst classes, who are on short sentences, and work only at boot and chair-making.

Other penal institutions, in their financial success, prove the fact that work-houses for inebriates, whose terms are long and who are not treated as outlaws, but as members of a community, can not only be successful, but will restore a large number of its inmates to health and society. Of all classes that society is called on to control by law, the inebriate, as a rule, is more capable of being self-supporting, and formed into work-house communities for care and treatment. Many of the inebriates who now suffer in jails are incurables, but in work-house hospitals they could be quaran-

trained from society, and under the direction of proper managers, be made self-supporting, if nothing more—an inestimable gain to their friends, society and the State.

Others of this class are curable from the application of exact means to meet such cases, and may be returned to society and the world useful and honorable citizens. It is a question not of financial management or proper laws alone, but the adaptation of means which shall build up the debilitated mind and body of the patient—a system of treatment in which all the surroundings and influences controlling the inebriate may be under the direction of a scientific hand.

Laws are essential to enforce the dictates of science, and good management to increase the efficiency of the work. This treatment will not only diminish inebriety by lessening the number of incurables and preventing contagion from this class, but it will do more than all other combined efforts to educate society to avoid the causes of inebriety, and the means of reaching this evil at its fountain head. This will be apparent from a general outline of the workings of such an institution.

The building should be located in the country, built from funds derived from a tax on the sale of liquor, and to accommodate from one to two hundred patients. A large farm should be attached, upon which all the various operations of farming and stock-raising may be conducted by the inmates; also workshops, where various mechanical labors may be carried on. The inmates to be placed under a semi-military discipline, in which all the surroundings and habits of life are regulated with great exactness.

Every patient should be treated medically, and by the Turkish baths, electricity, and all other appliances known to science, to build up the debilitated nervous system. Excellent food, pleasant rooms; and the salutary influences of libraries, papers, lectures, concerts, and religious services, should be had. Regular employment, not exhaustive, on farm or in workshop, particularly that kind which is remunerative and congenial to the patient, would be important curative factors.

Here, removed from all temptations, with the quiet and regularity of these surroundings, and where the above-mentioned agencies are used, permanent cures should be the rule.

These institutions, by requiring their inmates to pay reasonable charges for board, should be self-supporting, particularly when the patients receive compensation depending upon their skill and energy.

Thus, after a few months' treatment, the patient

recovers much of his physical and muscular vigor, and is able to do as much as he did in health. In this way the employment serves the double purpose of strengthening and hastening a restoration of the nervous system, and giving physical vitality to all the organs, in the independence of being self-supporting. This practical character of such institutions is supported by evidence from all jails, hospitals, and reformatories in the country, and from the observation and experience of physicians who have treated inebriates.

The practicability of utilizing labor and energy of this class, in making them self-sustaining, admits of no reasonable doubt. The result is only a question of the facilities and surroundings. As a matter of fact, the State of Massachusetts, in the conviction and punishment of fourteen thousand inebriates, expended three hundred thousand dollars, and increased the burden of the tax payers, with no result except to perpetuate the very evils those means were intended to correct. Had these inebriates been confined in work-house hospitals, this large amount would have been saved, besides a great loss to their friends and the communities in which they resided, by changing a multitude of non-producers and persons dangerous to society, to a condition of self-supporters and orderly citizens. The criminal class should be made to sustain itself. A large portion of insane persons, and the still larger number of inebriates, paupers and vagrants, who fix themselves upon society like parasites, should be made self-supporting; and the reality of this will be confirmed from a wider and fuller comprehension of this subject. A mere restraint from alcohol without other means cannot cure inebriety; because the disorder is generally a result of many causes, of which alcohol is only one, and in a large number of cases is only a symptom. But any system of treatment that does not include restraint from alcohol will be imperfect, and produce unsatisfactory results. The State treatment which affords only one curative factor, namely, restraint from spirits, must always fail. To this must be added all the appliances and means of a home, asylum, or institution with exact care and treatment. The combination of such means carried out scientifically with a proper degree of discriminating as to class, sex, age, and condition of the patient, success would be the rule, failure the exception.

The inebriate should be regarded an object of public care, where he does not provide for his own interest and neglects all ordinary duties. Most inebriates who are arrested at this day, belong to

a low chronic class, and have squandered their property, distressed their families and friends, and violated good order and decency by becoming publicly intoxicated. These were arrested because of their continuous excessive use of alcohol, with stupor and delirium, which renders them public nuisances. Most of these unfortunates are, unconscious of the nature and character of their acts. The desire for spirits has waxed into a diseased impulse, which has perverted all healthy functions of body and mind. All appeals to their reason, pride, and reputation are useless; however sincere and earnest they may be to respond, the functional activities being too weak to enable them to do so. The mind and sufficient will power to desist can be reached only through the organism, by restoring gradually a normal activity of the brain and the nervous system; and all methods and means which produce this result, are in a line to permanent recovery. Inebriety, like insanity, is a peculiar disorder of the great nerve centres, with diverse complex symptoms, which can only be reached by special adaptations to the organism and its functions.

A common illustration to be seen in almost any community will still more strongly confirm the folly of penal treatment. John Doe, born of healthy parents, and brought up on a farm, became a robust, vigorous boy. At sixteen he was attacked severely by typhoid fever. From this he never fully recovered, and afterwards suffered general debility and much weakness from a feeling of over-exertion. He became a grocery clerk, and at twenty drank to intoxication, at long intervals. At this time acquiring a large property by inheritance, he ceased all attention to business, traveled about, drank freely, and lived mostly a retired life, avoiding fast associates, and generally excluding himself from fast society. In a few years he was a bankrupt, and later being convicted of drunkenness, he was sentenced to jail, for ninety days. Having served out his term of punishment, having lost all pride and ambition to do any good thing, he associated with low characters, and sought to gratify the basest impulses of his nature. Within the next six years, he was convicted eight times and sent to jail. When attacked with a violent form of acute rheumatism, he was taken to almshouse and died.

Robert H. was born of neurotic parents, was sensitive and nervous during childhood, and attaining manhood studied for the ministry. After a disappointment in love, he began to drink; gave up his studies, and became a book-agent. At the age of twenty-four, he was sent to jail for

drunkenness and breaking the peace. When released from jail, he began a career of petty thieving and drunkenness, with acquaintances formed when in prison. In the next ten years, he was convicted fourteen times for petty larceny and intoxication, was committed to prison, and served out each term. He died from injuries received while in a condition of intoxication.

Carlos B. was of unknown parentage, a healthy and temperate machinist, and highly esteemed by his acquaintances. After a long course of beer-drinking, he became intoxicated, and destroyed some property; was convicted and imprisoned. After being discharged, he became a bar-keeper and gambler, and associated much with a criminal class. He was sent to jail frequently for drunkenness and violation of the law, and finally was sentenced to imprisonment for life, as an accessory to a murder.

Oscar V., a Swede, with no ancestral history, was temperate, and a musician of skill. After an attack of small-pox, he began to drink. He signed a pledge, attempted many times to reform, but as often relapsed. In one of these relapses he committed crime; he was sent to jail for thirty days. When released at the end of his term, he associated with the lowest class of persons, and drank steadily without any effort at reforming. About every three months afterward he was often imprisoned for drunkenness, during a period of several years, when all traces of him were lost.

These are familiar cases in police practice and to jailors, and are convincing protests against the folly of checking inebriety by such means. The physician should be an educator, and teach the public how to adapt curative means to reach drunkenness; then legislation would be practical, and this disease would be curable as any other. No progress can be expected in legal methods until they are founded on an exact knowledge of the disorder and its remedies.

A NEW REMEDY FOR THE VOMITING OF PREGNANCY.

BY T. C. WALLACE, M. D.,
Cambridge, N. Y.

I know of nothing in the whole range of practice so discouraging to the physician, so unsatisfactory to the wretched patient, and so calculated to cause distrust in the resources of our profession, as a case of the severe and protracted vomiting which so often attends the parturient state. Prof. Horwitz, in speaking of the treatment of this disorder, aptly remarks: "The legion of drugs for this disorder is the best proof of their

utter worthlessness." For the past four years I have used for this complaint a simple remedy, which has uniformly given me great satisfaction, having *always* found it a *beneficial* and *generally* a *sufficient* remedy. It is the quickly-roasted grain of a species of Indian corn, too well known as pop-corn to need any description. It should be popped in a wire popper, not (as is sometimes done) in a spider with grease; should be white and light, sprinkled with a little salt, and eaten freely. I might state many cases in which this simple remedy has "acted like a charm" in this disorder, but will content myself with the relation of the following one:

On the 8th of January, I was called to visit a lady advanced a little over three months in her first pregnancy, who had suffered from almost constant nausea and uncontrollable vomiting from the time of her conception. I found her in bed, to which she had been confined for more than four weeks, pale, languid, depressed in spirits, pulse 120, feeble, and so prostrated as to be unable to raise her head from the pillow. For the past sixteen days her stomach had absolutely refused to retain anything; everything—food, medicine, even a swallow of water, being instantly rejected. During the past six days, absolutely nothing had been taken into her stomach; all nourishment and medicines having been administered per rectum. Even then she had constant nausea, almost continuous violent retching, and frequent vomiting of bilious matter. For a long time she had been under the care of a respectable practitioner, who had faithfully tried nearly all the usual remedies (?) for this complaint. Fowler's solution, oxalate of cerium, bismuth, ingluvin, "*et id omne genus*," had been given internally. Cope-man's method of dilatation, nitrate of silver in substance and in saturated solution, had been applied to the os and cervix. Sinapisms, hypodermics of morphia, ether spray to the epigastrium and spine, injections of bromide potass. in beef tea, and I cannot remember what else, had all been faithfully and unavailingly used. Some pop-corn was immediately prepared, a little salt sprinkled thereon, and of which she ate a large saucerful. At my call next day, found she had passed a quiet night, without nausea or vomiting, and had eaten very freely of the pop-corn. She has had no further trouble. January 25, as I was passing her house, I saw her at the door. She informed me that since my first visit she has vomited but once, and then but slightly. Sometimes has slight nausea, which is always relieved by eating some pop-corn.

The remedy is so simple, so easily procurable, so utterly harmless, and with me has always proved so efficacious, that I publish this in the REPORTER, confident that my professional brethren will find it singularly efficacious in the relief of this most distressing disorder.

CALIFORNIA AS A HEALTH RESORT.

BY J. S. ADAMS, M. D.,

Of Oakland, California.

California, as a health resort, has attracted for the last twenty-five years more or less attention from the general public, and especially that portion who have visited the State in search of health; and that she justly deserves the reputation of being second to none, is an established fact, and fully capable of demonstration by any one who is acquainted with her great resources of climate.

Having come to this coast twenty years ago an invalid, and being fully restored to health, I wish to hint to the members of the profession in the East, who have not had an opportunity to know personally, some of the most desirable locations where invalids may come with the greatest hope of benefit.

After visiting many of the health resorts of Europe and America, I feel warranted in saying that for healthfulness of climate, California cannot be excelled. Not only is climate, but comfort and attractiveness, essential to the invalid; and while the first is of utmost importance, the others are valuable aids to recovery.

The health resorts of Europe have their disadvantages, such as periodical cold and sweeping winds, local malaria, foreign language, customs, and accommodations, which, as a rule, are inferior to those of America.

Florida, with its attractions, has a humid atmosphere, and more or less malaria.

Colorado, with some advantages, has extremes of temperature and severe winters.

California, on the other hand, occupying, as it does, an area of country lying between 32° and 42° north latitude, and extending from the Sierra Nevada mountains to the Pacific Ocean, presents the greatest variety of scenery and climate.

Within these limits you may find the semi-tropics of the South, or the eternal snows of the northern Sierras. Here is the greatest variety of altitude and temperature. Along the ocean, the land gently rises from the level of the sea to the summits of the coast ranges, an altitude of from two to four thousand feet.

From San Francisco to San Diego there are de-

lightful resorts to which thousands of invalids come in search of health. During the summer, the trade winds from the southwest, mingle with the Arctic currents, while in winter, the warm currents of air, direct from the tropics, give an evenness of temperature, and a bracing character to the climate, especially along the coast, which is unexcelled, if equaled, on the globe.

The mountain climate for those who have disease of the lungs is delightful in summer, and the altitude generally most beneficial is from one to four thousand feet; of course depending upon the condition of the patient and accommodations offered.

Along the Sierras there are numerous places of resort, but those easiest of access by the invalid are along the line of the Central Pacific railroad, from Auburn, with an elevation of fifteen hundred feet, to Lake Tahoe, which is six thousand feet above the ocean level. At most towns along this route comfortable accommodations can be obtained.

Along the coast range of mountains, from Santa Barbara on the south to San Francisco on the north, the climate is delightful, and generally more even than that of the Sierras, on account of the more or less direct influence of the ocean breezes.

Here I wish to emphasize the remark that, *persons with organic disease of the lungs in an advanced stage should always remain at home, where they can have the loving attention of family and friends.*

I have had many call upon me for advice who were sent to the coast with consumption and beyond recovery, asking the best course to pursue. My invariable reply to those cases is, "If you wish to die among your friends, you will do well to return at once."

The mineral springs of California are *legion*, and many of them upon analysis compare favorably with any of those in the East or Europe; but of these I propose to speak at some length on another occasion.

One object at the present time is to call attention especially to the advantages of some locations on this coast as a winter resort for Eastern invalids. There is a multitude of people in the East who are suffering from bronchial difficulties, incipient consumptions either hereditary or acquired, and nervous exhaustion from over-work and various other causes, who dread a long, cold, and changeable winter. To those I would say, we have a climate and resorts superior to most and second to none in the world.

The coast from San Francisco to San Diego, in

winter is fanned by breezes coming from the tropics, beautifully tempered and richly laden with the elements necessary for increased vigor and returning health.

It is generally conceded that an even and proper temperature, good diet, pleasant surroundings, and the comforts of a *home*, are the *sine qua non* for both the invalid and pleasure-seeker.

Below will be found a carefully prepared table of the mean temperature for a series of years of various places of resort, which is worthy of examination and careful study:

PLACE.	JAN.	JULY.	DIFF.	LATITUDE.	
	deg.	deg.	deg.	deg.	min.
Monterey . . .	52	58	6	36	36
Santa Cruz . .	52	61	9	37	00
San Francisco .	49	57	8	37	48
Los Angeles . .	55	67	12	34	04
Santa Barbara .	56	66	10	34	24
San Diego . . .	57	65	8	32	41
Santa Monica .	58	65	7	34	00
Sacramento . .	45	73	28	38	34
Stockton	49	72	23	37	56
Vallejo	48	67	19	38	05
Fort Yuma . . .	56	92	36	32	43
Cincinnati . . .	30	74	44	39	06
New York	31	77	46	40	37
New Orleans . .	55	82	27	29	57
Naples	46	76	30	40	52
Honolulu	71	77	6	21	16
Funchal	60	70	10	32	38
Mentone	40	73	33	43	71
Genoa	46	77	31	44	24
City of Mexico .	52	63	11	19	26
Jacksonville . .	58	80	22	30	50
St. Augustine . .	59	77	18	30	05

While it will be seen that Monterey, Santa Cruz, Santa Barbara, Santa Monica, San Diego and Los Angeles are the most desirable of the many Pacific coast resorts, for a locality combining all the requisites before mentioned, I consider that Monterey stands at the head of the list. It is delightfully situated at the south-easterly extremity of Monterey Bay, about one hundred and twenty-five miles South of San Francisco, and connected with it by the Southern Pacific Railroad, which passes through some of the most fertile and beautiful valleys in the State. Here there is security from cold winds and excessive mid-day heat.

Contrary to the generally conceived opinion that we have an almost continuous rainfall in the winter, this season is more like the eastern spring weather in May and June, and during the rainy season, or winter months, we have more sunny days than any other portion of the United States.

At Monterey, the diversified scenery of bay,

forest, and mountains, the beautiful drives through groves of pine, oak, and cypress, and along the ocean beach, are sources of interest to the visitor, while the clear water of the bay and white sandy beach invite those who are fond of sea-bathing.

HOSPITAL REPORTS.

EYE CLINIC AT THE MICHIGAN COLLEGE OF MEDICINE, DETROIT.

BY C. J. LUNDY, A. M., M. D.,

Professor of Diseases of the Eye, Ear and Throat.*

Case 1. Gummy Tumor of Iris, with Iritis.

The first patient is Miss Blank, æt. 24. Some days ago she came to consult me regarding a painful affection of the eye, which had become inflamed four or five days previously. I first saw this patient about six months ago, at which time she came to consult me regarding a throat affection, which proved to be syphilitic. She denied having contracted syphilis, at least in the usual manner, and examination did not reveal any evidence that it was so contracted. Upon the lip, however, I discovered a suspicious-looking, swollen, indurated spot about as large as a silver quarter. This, she informed me, had been a "cold sore" which did not heal for more than two months, notwithstanding that it had been locally treated by a physician most of the time. Whether the real nature of the sore was known to the physician, I am unable to say.

Upon interrogation, I learned that this young woman had a lover who was in the habit of kissing her, and that this lover had a suspicious-looking eruption upon his face.

Now, what bearing has this bit of history upon the case? Just this: In my opinion this patient contracted syphilis from her lover, and that the so-called "cold sore" upon the lip was the initial lesion which led to her constitutional disease. Although primary syphilitic sores are not frequent upon the lips, yet they are occasionally observed. Whether the sore upon the patient's lip was truly a hard chancre, is a question which I am unable to decide, for it had healed when I first saw her.

Some time since there was some discussion as to whether a secondary syphilitic sore produced a secondary sore or a chancre. I presume the sore upon the lip of the girl's lover—the sore whence came the virus which poisoned her system—was a secondary sore.

Under treatment her throat affection got well, the mucous patches and superficial ulcers healed, and all signs of active syphilis disappeared. The disease was not cured, however, and of this she was fully warned. She disappeared, and I did not see her again till four or five days ago. So much for her history. She now tells us that her left eye is very painful, and that for several nights the pain has prevented sleep. This pain is not confined to the eye, but involves the supra-orbital region and temple of the left side. The side of

the nose, and even the cheek, are also more or less painful. In a word, the pain follows mainly the branches of the ophthalmic division of the fifth nerve. She also tells us that her vision in this eye is greatly impaired, and that exposure to light increases her suffering. These are mainly the subjective symptoms.

What are the objective signs? As you examine the eye, you will observe that there is much ciliary congestion; that the pupil is irregular instead of being round; that it does not respond to light, and that it is in part filled with a large, brownish nodule, which seems to have small spots of hemorrhage or intensely congested vessels upon its surface.

You will also observe the copious flow of tears, and the manner in which the patient shrinks from the light. You will also observe that there is no discharge from the eye except the tears; and this absence of discharge, with the acuteness and character of the symptoms, removes the possibility of your mistaking this for a conjunctival inflammation, as is so often done in similar cases. What, then, is the eye trouble of which this patient complains? I hear from several, "iritis." Yes, it is a case of iritis, and it bears a very close relation to her constitutional disease. In other words, this is a case of so-called syphilitic iritis, although it does not differ, in most respects, except in causation, from other cases of plastic iritis. The nodule which you have seen upon the iris and partially filling the pupil, is a gumma. Now, many authors tell us that you cannot distinguish iritis due to syphilis from other cases of iritis. That is so in the vast majority of cases, but I do not hesitate to state that, occasionally, we meet cases like the one before us, where the diagnosis of syphilitic iritis can be made from the eye appearances alone.

This gummy tumor in this girl's iris, like similar tumors in other localities, is composed largely of cellular elements and nuclei. If no treatment is instituted, the eye is liable to be permanently and seriously injured, while under appropriate treatment the gumma will soon disappear. In this case atrophic changes have already begun, and in the course of ten days, or even less, you will be unable to detect any evidence of it. By some authors we are told that gummy tumors of the iris occur very early, even before the chancre, or primary sore, has had time to heal. Others tell us that they occur only in tertiary syphilis. So far as my observation goes, neither of these views is correct.

It is now about ten months since this young woman contracted syphilis. Therefore, this eye trouble is not an early secondary lesion. In fact, it never is. All of the cases of gummy tumor of the iris which have come under my observation have occurred between the sixth and twelfth months after the appearance of chancre. In a word, they occur about the same time that syphilitic iritis generally occurs—neither very early nor very late. In our patient's case, the prognosis is good so far as the inflammatory action is concerned, but there exists between the iris and the lens capsule an adhesion which cannot be broken up by any mydriatic at our command. These adhesions, or synechiæ, as they are technically called, are some of the bad results of iritis.

* Reported Phonographically by John R. Arnold.

The local treatment of this case of iritis need not differ materially from that which would be appropriate in plastic iritis due to some other cause. The eye should be protected from light by means of a small dark patch, and the sound eye should be covered by a colored glass, for the light which falls upon the sound eye irritates the diseased one. Atropia sulphate gr. iv ad ʒj, or stronger, should be instilled into the eye four to six times a day. This is done for a two-fold purpose: First, to dilate the pupil as fully and as quickly as possible in order to prevent the formation of posterior synechiæ, or to break up (if possible) the synechiæ which have already formed. Second, to place the eye at rest, and limit the inflammatory action. If you succeed in dilating the pupil, you place the iris in the condition least favorable for inflammatory action. If you prefer to use some other mydriatic than atropine, you may do so, but the intoxicating effects of duboisia and the feeble action of homatropine do not warrant your forsaking the old friend for the new. Besides, they possess no advantage over sulphate of atropia in the treatment of iritis. In severe cases three or four leeches applied to the temple, or the artificial leech applied to the same place, is worthy of trial. You may give anodynes to relieve pain if necessary. The constitutional treatment in our patient's case does not differ materially from that usually followed in secondary syphilis. Mercurials, either alone or combined with iodide of potassium, are here indicated. This patient has taken the proto-iodide of mercury in half grain doses after meals till this morning, when the dose was reduced to one quarter of a grain. On one or two occasions it was necessary to give an opiate to prevent the too free action of the bowels. In this way the drug would be eliminated from the system, and the constitutional effects would be slight were the action of the bowels not controlled. When syphilis attacks such a delicate organ as the eye, prompt action is necessary. Very often your patient's stomach will not tolerate free doses of the mercurials, and then inunction may be resorted to with advantage. The mixed treatment also acts well in many of these cases, especially when the iritis occurs in the late secondary stage. But whatever your plan of treatment, do not injure your patient with large doses long continued. As soon as the disease shows signs of coming under control, diminish the dose.

Case 2. Double Iritis due to Rheumatism.

Wm. J., æt. 40. This patient is also suffering from iritis, and as the two cases have many points in common, I shall now consider this one at length. This patient gives a history of several attacks of iritis in both eyes. As you examine the pupil of his right eye, you will observe it is greatly contracted, and is immovable. The pupillary margin is entirely adherent to the lens capsule, and our efforts to dilate the pupil have been futile. The appearances of the eye and the symptoms, both objective and subjective, do not differ essentially from those present in the preceding case. In the left eye of this patient there is evidence that the whole pupillary margin is not adherent, for you observe that the pupil is dilated upward. For years this patient has had occasional attacks of rheumatism, and his iritis is what is sometimes

spoken of as "rheumatic iritis." The older authors classified iritis according to its supposed cause, but this was unscientific, and now cases like this, as well as cases like the preceding one, are classed as plastic iritis. The term "plastic iritis" has the advantage of conveying to our mind some idea of the nature of the inflammation. In plastic iritis like this, the inflammatory product is mainly fibrinous in character, and is capable, under certain conditions, of becoming organized tissue by metamorphosis. When synechiæ remain after iritis, I think they predispose to subsequent attacks, and this may, in part, account for the frequent attacks which this patient has had.

In this man's case, the synechia has become annular in the right eye from these recurring attacks, and this leaves the eye in danger. The natural passage between the anterior and the posterior chamber is closed. The fluids of the eye, which filter through by osmosis from the back to the front of the eye, and find their exit from the anterior chamber, can no longer pursue their natural course, and as a result of this obstruction, there is a liability to increased tension or hardening of the eyeball. Should this occur, it would lead to disastrous consequences, but I cannot now take time to enumerate these or to pursue them further, however interesting they might be.

Now, what can be done for this patient? I have already told you he was of a rheumatic diathesis, and this would suggest your plan of internal treatment. In cases like this, I have usually found much benefit from the administration of the salicylate of soda in free doses. You must give it freely in order to get the desired effect. With its use patients usually recover much sooner than without it. Potassium iodide may also be administered with advantage in certain cases. This is especially so if the rheumatic patient has ever had syphilis. I have seen iritis in so many rheumatic patients, who contracted syphilis years before, that I have sometimes thought they were more liable to iritis than were others. Our local treatment does not differ essentially from that pursued in the preceding case, except that this patient needs an operation, which will be performed as soon as the inflammation subsides. I shall make an iridectomy upon this man's right eye in the near future. The object of this will be twofold. First, to establish a communication between the chambers of the eye, in order to guard against the dangers already referred to; and, second, to give him an artificial pupil for visual purposes.

Case 3. Divergent Squint Corrected by Section of the Rectus Externus and Advancement of the Rectus Internus.

The next patient is Miss M. M., æt. 28. As you examine her eye, you will observe that it turns far outward when she looks at any object in front. In normal eyes the retinal images of an object are formed upon portions of the two retinae, which correspond to each other, and thus binocular single vision results. If, however, one eye deviates outward or inward, upward or downward, the result will be a disturbance of vision and the images will be seen double instead of single. In our patient's case, rays of light reflected from an object in front do not impinge upon the cornea of the right eye at the same angle that they do upon the

left cornea. The rays enter the right cornea obliquely, and images are formed upon the temporal side of the retina; while upon the left retina images are formed in the region of the yellow spot or fovea centralis. In this case there is no proper correlation of the visual axes, and she sees objects double, for the images are not formed upon corresponding portions of the two retinae.

However, the double images in this particular case are not very annoying, and it is not on that account she seeks relief. To some extent she has learned to "suppress" the least distinct image, viz: the one formed upon the retina of the right eye. In other words, she does not take mental cognizance of the second image. At best, her sight in the right eye is poor, and we cannot improve it. She comes to be relieved of her deformity—to get her "eyes straightened," as she puts it—and the object of treatment will be cosmetic effect, rather than improvement of vision. Strabotomy is usually the plan resorted to for the correction of squint. As you have observed in numerous cases, this procedure has corrected squint of high degrees. In this case, however, I do not think section of the external rectus would correct the divergent squint. It will be necessary to advance the internal rectus to obtain the desired result, but we will first snip the external rectus and observe the effect. As you see, the operation has not entirely corrected the outward squint, and, as predicted, it will be necessary to advance the insertion of the internus to give it greater control over inward movements of the globe. This is usually done about as follows: The lids being held apart by an eye speculum, with an ordinary fixation forceps, the conjunctiva and subconjunctival tissue, a little anterior to the insertion of the internal rectus, are seized, and with scissors section of these tissues is made, as in the first steps of a strabotomy. You observe that a narrow band of conjunctiva and subconjunctival tissue is left between the incision and the corneal margin. The tendon of the internus is now made bare, and with this strabismus hook, I now bring it well into view. While an assistant holds the muscle with the strabismus hook, I pass through its tendon behind the hook these two needles loaded with black silk. The next step is section of the tendon close to its insertion. Now I bring the cut end of the tendon forward, and stitch it to the bridge of conjunctiva, left for this purpose between the corneal margin and the incision in the conjunctiva, and for this object I employ the threads passed through the muscle previous to detaching it from the globe. I now unite the conjunctival wound by two stitches, bringing the one well below and the other above the two which unite the tendon to the bridge of conjunctiva. These last two stitches should dip deep, and embrace as much of the subconjunctival tissue as possible, and thereby prevent strain upon the muscle till it has firmly united in its new position. You now observe that the squint is entirely corrected, and that the eye no longer deviates outward.

Readjustment has been advocated as the proper method of correcting squint in all cases. This may be well in theory, but in practice the operation of strabotomy, as ordinarily performed, gives most satisfaction. The after treatment will con-

sist of the application of a light compress bandage for a couple of days to keep the eye at rest, until the parts have healed, at which time the stitches should be removed.

MEDICAL SOCIETIES.

ILLINOIS STATE BOARD OF HEALTH.

The regular annual meeting of the Illinois State Board of Health was held in the office of the Board, in the Capitol building at Springfield, the members being called to order by the president at 7 p. m., Thursday, January 11, 1883, and continued in session throughout the evening of the 11th and the 12th.

Present: John M. Gregory, Newton Bateman, W. A. Hasdell, John H. Rauch.

It was reported that since the advent of cold weather a few scattering cases of small-pox had occurred; and it was found that the victims were, in every instance, either unvaccinated or not vaccinated since infancy or childhood.

Dr. Rauch, the Secretary of the Board, reported as follows:

"There have been no cases among immigrants during the quarter—none, in fact, since the single case in the early part of June last, soon after the sanitary inspection of immigrants was begun. Strenuous efforts have been made to secure the continuance of these inspections, or, at least, their prompt resumption at the opening of the immigrant season. Among other contributions to this end, I have prepared and published a paper on the 'Immigrant Introduction of Small-pox into the United States,' in which I think is demonstrated—from the history of small-pox in Chicago during the past thirty-two years, from the consensus of statements of leading health officials concerning the origin and spread of the recent epidemic, and from the results of the operations of the Immigrant Inspection Service—

"1. That the immigrant is a prime factor in the origin and continuance of small-pox in the United States.

"2. That State and local boards of health, acting independently, cannot suppress the disease, when once introduced, so long as the influx of unprotected immigrants continues.

"3. That the immigrant inspection system, in addition to furnishing a practical mode of co-operation by the various State and local boards of health, has proved entirely adequate to the remedy of the defects arising from want of international quarantine laws, and of uniformity in the administration of our own maritime and boundary quarantines.

"A total of 115,057 immigrants were inspected in the District between June 1 and December 31, 1882. Of this number 57,302 were found to have been satisfactorily vaccinated before sailing or during the voyage, and 3,127 were found to have had small-pox—making about 53 per cent. of the total number protected. There were 28,408 of the remainder vaccinated or revaccinated after arrival and before reaching this district; and 21,618 similarly treated by the Western inspectors; leaving 4,602 unaccounted for, including those whom it was deemed inadvisable to vaccinate.

"At the close of August I made a table of the results obtained up to that time. There had then been an aggregate of 63,962 persons inspected, of whom it was found that 54 per cent. were imperfectly or entirely unprotected against small-pox on arrival; and that only 22 per cent. were vaccinated on shipboard. These figures have been changed, by the pressure and influence of the Inspection Service upon the steamship companies and their surgeons, so that, for the whole season, the percentage of 'susceptible' was reduced to 47, while the proportion of ship-vaccinations was increased to 29, in the hundred.

"This latter figure (29 per cent.) represents an actual increase of fully 42,000 vaccinations secured on shipboard by this means, during the latter, as compared with the first half of the season; and indicates the increasing value, efficiency and influence of the service, both directly and indirectly, at the time when its operations were suspended.

"As a result of the existence of the service, about 174,000 vaccinations on ship-board have been obtained among the arrivals at all ports.

"The exposure of the Boston Bellevue Medical College, and its consequent disruption, of which the members have already been advised, have been followed by some unlooked-for developments: As a result of the correspondence carried on from this office, the most convincing proof was secured that the so-called 'college' sold diplomas and degrees to individuals grossly ignorant of any medical knowledge, and either with or without attendance upon its alleged course of instruction. Its officers were arrested for using the United States mails for fraudulent purposes, and, on trial, admitted all that was charged against them, except violation of the postal laws. To this charge they pleaded that they were legally incorporated, and were empowered by the laws of Massachusetts to issue diplomas and confer degrees, without any restriction as to course of study or professional attainments. The United States Commissioner held the plea to be valid, and dismissed the case with the following remarks:

"The State has authorized this college to issue degrees, and it has been done according to legal right. * * * The law makes the faculty of the college the sole judges of eligibility of applicants for diplomas. There is no legal restriction—no legal requirement. *If the faculty chooses to issue degrees to incompetent persons, the laws of Massachusetts authorize it.* This is, therefore, not a scheme to defraud under the statute. The defendants are dismissed."

"Since this decision was rendered—that is, within a fortnight—the 'American University of Boston,' president Dr. Buchanan (familiar name in this connection), and the First Medical College of the American Health Society, located at Boston, have been incorporated, and Dr. Alfred Booth, the first president and one of the incorporators of the 'Boston Bellevue,' has given notice of his intention to start the 'Excelsior Medical College.'

"What Dr. Joseph Corken, one of the 'Boston Bellevue' faculty, arrested in November for procuring abortion, and charged with carrying on a wholesale business in this line under the name of the English Cottage hospitals; and Dr. C. J. Eastman, the 'dean' of the now defunct 'Belle-

vue,' alias 'Old Dr. Edwards, 18 Dover street, Boston, no-cure-no-pay-secrecy-preserved;' and Dr. Rufus King Noyes, the anti-vaccinationist, will now do, remains to be seen—probably act upon the suggestion of the *Boston Medical and Surgical Journal*, and each 'join himself with his uncle and his neighbor, who is like-minded with himself, and become incorporated under the laws of Massachusetts.' The pious ejaculation of the editor in closing his article seems entirely appropriate—'God save the Commonwealth of Massachusetts!'"

The recent exposure of a barber named Lambrecht, who presented a diploma from the University of Göttingen issued to Dr. Henry A. Lüders, and who received a certificate from the Board of Health, which was subsequently revoked, makes a total of thirty-one cases of individuals who have been detected in falsely swearing to be graduates of foreign universities, their pretensions exposed, and the imposters driven from the State through the Act to Regulate the Practice of Medicine.

On the whole, the school population of Illinois is now quite well protected against small-pox.

A Proposed Sanitary Convention.

Dr. Newton Bateman, the chairman of the committee appointed at the last quarterly meeting, to prepare a uniform Sanitary Code for the guidance of local boards of health, having progressed with the work, recommended the calling of a convention of representatives of all health organizations or departments in the State of Illinois, and inviting the authorities of every village, town and city in the State, having a population of one thousand or over, and in which there is no health organization or department, to send one or more delegates to said convention.

The Committee on *Prevalent Preventable Diseases* presented a report in which it appears that of every thousand deaths in the State during the past year, it is estimated, on the basis of returns in the Secretary's office, one hundred and thirteen were due to scarlatina, diphtheria and typhoid fever, in about the following proportions: 17 from scarlatina, 45 from typhoid or enteric fever, and 51 from diphtheria. On the same basis it is estimated that 82 out of every thousand deaths were caused by cholera infantum; while nearly 250 out of every thousand deaths were of infants under one year of age, and 43 were of children under five years of age.

That this enormous mortality among children is largely preventable cannot be questioned, and your committee would, therefore, suggest the preparation of a pamphlet of instructions upon the Hygiene of Infant Life, or the sanitary care of infants and children, for widespread distribution before the advent of the summer months, which are so destructive to early life.

Dr. Haskell presented the following preamble, resolutions and memorandum, which were unanimously adopted:

NATIONAL BOARD OF HEALTH.

"WHEREAS, The act of Congress, approved June 2, 1879, by which the National Board of Health is charged with the duty of co-operating with and aiding State and local boards of health in the enforcement of their rules and regulations to prevent

the introduction of contagious and infectious diseases into the United States, and into one State from another, will expire by limitation on the 1st of June, proximo; and

"WHEREAS, The said National Board of Health has discharged this duty with so much of success, honesty of purpose and regard to economy—the specific details of its work being briefly summarized in the appended memorandum—as to conclusively demonstrate the value of a national agency for the protection of the public health; therefore, be it

"Resolved, That the Illinois State Board of Health earnestly urges upon the Senators and Representatives from this State to obtain, during the present session, the legislation necessary to secure an extension of said act, pending the creation of a permanent national health organization—such legislation to include a provision whereby the unexpended balances of the original appropriations may be reappropriated and made immediately available for the purposes of said act.

"Resolved, That the Secretary be, and he hereby is, authorized to transmit a copy of this preamble, resolutions, and appended summary to each Senator and Representative from this State."

Then followed a memorandum eulogizing the National Board. The remainder of the morning session and the entire afternoon was occupied with questions arising under the Medical Practice Act, in which the status, methods and reputability of a large number of medical colleges and practitioners were involved.

A communication was read from I. M. Browne, Medical Director U. S. N., in charge of the Museum of Hygiene, asking for contributions to the Museum. The Secretary was instructed to furnish a set of the publications of the Board.

At the evening session, after the transaction of routine business, the President announced that the election of officers was next in order, whereupon Dr. Haskell offered and moved the adoption of resolutions of thanks to the retiring officers.

In seconding the motion for the adoption of the resolutions, Dr. Bateman spoke of the work which had been accomplished, its pioneer character in many respects, the multiplying evidences of popular appreciation coming under his observation, and the gratifying recognition of the Board in the following passage from the Governor's recent message:

"At the time of the organization of the Board of Health, there were doubts in the minds of many good people as to its necessity, and for a time, much prejudice against its work. The doubts and prejudices, however, have gradually given way, as the Board has fearlessly and with prudence gone forward in the discharge of the work before it, until I think there is now an almost universal conviction that its services in protecting the people from contagious diseases and from the evils caused by ignorance and charlatanism in the practice of medicine, as well as the general sanitary work of the Board, cannot be dispensed with. The acts creating this Board and conferring its powers would have proven a dead letter if not enforced, as they have been, by a competent and determined executive agency; and it will be a gratification to the people of Illinois to know that in their enforcement the State Board of

Health has exerted an influence which has been felt throughout the country in various ways, in the elevation of the standard of medical education, the suppression of fraudulent medical colleges, and the introduction of improved methods of establishing and maintaining an effective quarantine against infectious diseases. Their services have done much to add to the reputation of our State at home and abroad."

Dr. Gregory, in suggesting that the Board proceed to the election of a presiding officer, took occasion to thank the members for the honor they had conferred upon him during his two terms, briefly reviewed the labors of the Board during the period, congratulated his colleagues upon the results already accomplished and upon the promise for the future, and closed by nominating the Hon. Newton Bateman, LL. D., for President.

The result of the election, then held, is as follows: President, Hon. Newton Bateman, LL. D., of Galesburg.

Secretary, John H. Rauch, M. D., of Chicago.

Treasurer, A. L. Clark, M. D., of Elgin.

On taking the chair, Dr. Bateman made the usual acknowledgments, and spoke in warm terms of his predecessor in the office.

On motion of the Secretary, the members of the Auditing Committee, John McLean, M. D., of Pullman, and W. A. Haskell, M. D., of Alton, were reappointed for the ensuing year, and the Board, at 11 p. m., adjourned its Sixth Annual Meeting *sine die*.

Mistake by Druggist—Injury to Patient—Damages.

An action was brought against a druggist to recover \$10,000 damages for causing the death of a pregnant wife and the child that was born. These deaths, it was alleged, were caused by a dose of sulphate of zinc, a deadly poison, given by the druggist in mistake for Epsom salts. A judgment was recovered for \$1,000, and the defendant appealed the case—Walton vs. Booth—to the Supreme Court of Louisiana, which affirmed the judgment. The Chief Justice (Bermudez), in the opinion, said: "Though the death of the mother and child resulted from erysipelas, and not from the poison, from taking that the mother endured continued and great pain and suffering, for which she would have been entitled to recover. The defendant was greatly negligent. Druggists in the discharge of their functions should be required not only to be skillful, but also exceedingly cautious and prudent, in view of the terrific consequences which may attend, as they have not infrequently in the past, the least inattention on their part. All persons who deal with deadly poisons are held to a strict responsibility for their use, and a druggist is undoubtedly held to a special degree of responsibility for the erroneous use of poisons, corresponding with his superior knowledge of their dispensation."

MANY of the tribes of Eastern and Northern Siberia, chief of which are the Samocids, the Ostiaks, and the Kamtschadales, use the puff-ball fungi to produce a state of inebriety. The effects are a pleasant state of delirium, and unconsciousness of all trouble and sorrow, rarely developing the lower animal passions.

EDITORIAL DEPARTMENT.

PERISCOPE.

Syphilitic Disease of Knee Joint.

At the last meeting of the Mississippi State Medical Society, Dr. M. S. Craft reported (*Transactions*) the following instructive case:

"On the 8th of April, 1881, there was sent me from Clinton, by Dr. Whitfield, a knee-joint case of interest, an account of which I will give you.

"The patient was a white man, 35 years of age, with a syphilitic history. He had a chancre seven years before, followed by throat symptoms, and in time by a sore shin, probably a node, with ulcers upon the leg that healed very slowly, leaving behind purplish blotches, that were plainly to be seen at my first examination. He had never had constitutional treatment, and yet all active manifestations of the disease had subsided, and had not been noticed for years.

"Three months before he came to me, while splitting a plank with a short-handled axe, he struck the knee with the end of the handle, inflicting a slight injury, without breaking the skin. This pained him for awhile, but he continued his work, and from day to day kept on his leg, notwithstanding it was painful and sometimes swollen. It was a month or more before he was forced to bed, and longer still before he called a doctor; ultimately came to his home at Clinton, and then to me, by the advice of Dr. Whitfield. I found the knee red and enormously swollen, and the slightest movement or pressure giving great pain. The temperature was 104 $\frac{1}{2}$, and the pulse over 120. I explored the joint with a hypodermic needle, and drew out pus. This was a grave condition of things. A knee-joint full of pus from an injury that would have given no trouble but for the syphilis, indicated the tertiary stage in full blast. Amputation was duly considered, but certainly, with that temperature, pulse, and advanced constitutional infection, was, to say the least, very questionable; but the patient himself decided not to lose his leg, and I accepted, with many misgivings as to the result, the direction of treatment to save it.

"As soon as possible, I drew off the pus with an aspirator, and with the same instrument washed out the joint with tepid water, followed by a weak carbolated solution; put him upon the mixed constitutional treatment, mercury and iodide of potash, and gave him rich liquid food, with stimulants.

"On the next day, and every day for a week, I repeated the operation, finding at each morning visit the joint again distended with pus, and the temperature and pulse as at the first examination. I then tried solutions of salicylate of soda in place of the carbolate, increasing the strength at each injection, with no better result.

"As the pulse and temperature both came down at each emptying of the joint, and rose again as it refilled; and as pus continued to form, notwithstanding the injections, I determined to open the

joint freely with the scalpel, and did so at two points, giving perfect drainage to the pus as it formed, and a ready exit for the injections. This was followed by a most favorable change. The discharge rapidly decreased, and the general aspect of the case improved. But when the joint was looking most favorable, I found matter forming in the thigh above—and soon had to open large sinuses filled with pus, that ran in the direction of and nearly to the hip joint. This discharge, large in quantity, and most offensive in character, continued for weeks, and nothing lessened it or diminished the stench, until I remembered the permanganate of potash. With this, after carbolic and salicylic acids had signally failed, I could easily cleanse the pus-secreting cavities, and keep down all foul odors. Under its use, there was a change for the better.

"Thirty-five days had now elapsed, and notwithstanding the drain, my patient still had appetite and strength and hope, and for two weeks improved. Just then there was a general prevalence of diarrhoea; hundreds in the community were affected, and among them this poor fellow. All other cases got well without trouble, but his was obstinate, and would yield to nothing. Bowels continued to act until blood and pus appeared in the discharges, indicating, as I regarded it, syphilitic ulceration of the bowels, a condition from which recovery was impossible. He died June 23d, after being two months and a half under treatment with me.

"Amputation, in my judgment, would not have saved life at any time after I saw him; but, if at all, should have been done as soon as matter appeared in the joint. But I could not advise it in a tertiary syphilitic, with the pulse 120 and the temperature 104 $\frac{1}{2}$, to say nothing of the danger from hemorrhage after amputation, in a limb so greatly enlarged.

"Later, when the soft tissues of the thigh became infiltrated with pus, there could have been no healing of the stump; and still later, when the bowels evidenced the characteristic syphilitic ulceration, there was no power on earth to save life, and amputation would have been simply death upon the operating table."

Temperature in a Case of Belladonna Poisoning.

In the *British Medical Journal*, Dr. James McNab says that a case lately occurred in this town (Stirling) in which a child, between four and five years of age, whilst out playing with his companions, partook of some berries of the deadly nightshade, and some time thereafter had symptoms of narcotic poisoning. He took the berries between 5 and 6 p. m., and, having arrived at home in an hour or an hour and a half afterwards, asked for something to eat, when he was offered soup, of which he partook. Immediately after, he staggered and fell on the floor of the apartment. He had no vomiting. I saw him at 2 a. m., seven hours after the symptoms of narcotic poison-

ing had manifested themselves. I found him in a state of continual agitation and terror, with frequently recurring convulsive attacks; the pupils were widely dilated; the face congested and swollen, with dryness of the mouth and throat, and consequently frequent demands for something to drink. He had previously been delirious, laughing and singing, and imagining some one was thrusting berries into his mouth. Before my arrival, he had been given an emetic, and afterwards an aperient. The emetic brought up two half-digested berries and part of the soup he had taken. There being no doubt about the nature of the poison, he had aperient injections, cold to the head, a mustard poultice to the stomach, small doses of morphia, and stimulants, etc., administered to him.

Owing, however, to the length of time the poison had been working, and the gradual absorption of it into the system, there was little or no hope but that the case would have a fatal termination. The child died at twelve noon on the following day, seventeen hours after the first effects of the poison had been observed. I visited him an hour and a half before death, and found him in a state of coma. There was a tympanitic state of the stomach and bowels, which almost certainly pointed to an irritated and inflamed state of the alimentary canal. The chief noteworthy fact, however, was the excessive temperature. At the time of my last visit it was 110° , and it was this several hours before death. I have only observed this temperature once or twice in scarlet fever when death was imminent. To what could the high temperature be owing? Was it interference with the function of the sympathetic?

Intestinal Polypi.

Mr. Bowlby related the following cases at a recent meeting of the Pathological Society of London, which we note from *The Medical Times and Gazette*, December 30, 1882:

1. In a man, aged 64, who had had no intestinal symptoms, there were found diffuse polypoid growths throughout the colon, commencing just above the ileo-cæcal valve, and extending down to the sigmoid flexure. They were found in the mucous and sub-mucous tissues, and some were pedunculated. It was noteworthy that there was no stricture of the intestine. 2. A polypus removed from the rectum of a girl aged twenty-four, who had no intestinal symptoms beyond slight constipation. The polypus was attached to the anterior wall of the rectum, about four inches from the anus; it was soft and succulent, and covered everywhere by mucous membrane. It was accidentally ruptured during removal, and some turbid fluid escaped. After removal, it weighed two pounds all but an ounce. Its chief interest lay in its size. 3. A polypus of the small intestine occurring in a female child aged five. He gave the following history of the case: She was seized with pain in the abdomen suddenly one day; next day she passed some blood by the bowels, and during the next few days slime. She was admitted into St. Bartholomew's Hospital ten days after the commencement of her illness, with a mass protruding from the anus, which eventually came away, and a portion of which was recog-

nized to be the vermiform appendix. After this the child went on well, and left the hospital apparently recovered. Some months later she was brought back with symptoms of congenital syphilis, was readmitted, and died not long afterwards. At the autopsy the cause of death was recognized to be recent peritonitis. On opening the intestine, a polypus of fibrous tissue was found about eight inches from the anus; but evidently in the small intestine, and three inches and a half below this there was a transverse scar completely encircling the gut, where the small intestine, at what might have been the ileo-cæcal valve, had become adherent to the rectum or sigmoid flexure, so that the whole of the colon and cæcum had disappeared by sloughing. There was very slight constriction at the site of the scar. Mr. Bowlby remarked that when a polypus set up intussusception, it was usually the part to first present at the anus and be expelled. In this case it must be assumed that the polypus had set up increased peristaltic action of the intestines below it, and had never been actually involved in the invagination itself.

Dr. Coupland observed that polypi were not an infrequent cause of intussusception, and referred to the case of a young woman under his care in the Middlesex Hospital some two years ago, which had been published in the *Clinical Society's Transactions*, where an intussusception had been set up by a polypus in precisely the same way as in Mr. Bowlby's case. He also alluded to a specimen of multiple polypi of the colon in the Middlesex Hospital museum.

Mr. Cripps remarked on the enormous size of the polypus in Mr. Bowlby's second case; referring to the first case, he said that disseminated polypi in the colon were very rare; he referred to the specimen in the Middlesex Hospital museum, and also to one in the museum of Guy's Hospital; he said he had shown a specimen here last year, taken from a girl whose brother was also the subject of multiple polypi. He thought they began in a small collection of cells in the submucous tissue, which afterwards became a pedunculated tumor owing to straining. He considered the disease somewhat analogous to molluscum fibrosum, the tumors of which might easily be made to become pedunculated if pulled upon. In reference to the third case, he could not understand how the polypus could have been only three inches from the ileo-cæcal valve; the length of small intestine invaginated must have been equal to half of that of the colon, and the polypus must therefore have been more than a foot above the valve.

The President said that in his experience polypi in the rectum were commoner in small boys.

Mr. Henry Morris did not think polypi of the rectum so very rare. Quite recently he had seen a man with six or eight polypi in the rectum; he suffered a good deal from tenesmus. He wished to ask Mr. Bowlby whether his patient had had any symptoms.

Dr. Goodhart observed that there were three kinds of polypi—one fibro-cellular, covered over by mucous membrane, as in Mr. Bowlby's second specimen, of which he remembered to have seen one instance, though smaller than the one brought that evening; next, the firm mucous membrane polypus, well known in young boys; and thirdly,

disseminated pedunculated villous polypi. He could not agree with Mr. Cripps about the site of the polypus in the case of intussusception, and saw no difficulty in believing that it was quite close to the ileo-caecal valve.

Mr. Bowlby, in reply, thought the chief interest in his cases lay in the fact that the polypi were mucous, and not fibrous. He was of the same opinion as Mr. Cripps, viz., that a considerable portion of the small intestine—probably a foot—must have been lost.

Hydatid of the Liver.

Mr. Downes reports the following cases in the *Lancet*:

Case 1.—A middle-aged woman was seen in September, 1877. There was a large tumor extending from the liver to about two inches below the umbilicus; it was most prominent a little above the level of the umbilicus on the right side, and in one spot where it particularly bulged, distinct fluctuation showed that it contained fluid. The history of the case and the appearance of the patient seemed to indicate that it was not an abscess; there was considerable pain, but no fever, and the pain had come on gradually and seemed to be due to pressure only. Hydatid of the liver was diagnosed; and the tumor was tapped with a very small trocar and canula. The fluid withdrawn from it (which amounted to about half a gallon) was quite clear and non-albuminous. The tumor disappeared, and the woman experienced great relief. The patient remained quite quiet for some days. After about a week fever supervened, and there was tenderness at the spot which had been punctured. The fever disappeared, but a swelling was observed near the spot of puncture, and the tumor evidently contained fluid; this swelling increased for a few days, when it became stationary. The tumor did not extend below the level of the umbilicus. She remained in hospital for two or three weeks, when she returned to her home. She and her husband were very desirous that the tumor should be tapped again, but this was not done, as it was thought that it might become absorbed.

When the woman left the hospital the swelling had not materially decreased, but there was no tenderness, and the tumor extended only to about the level of the umbilicus, instead of occupying a large part of the right iliac fossa, as it did before the operation. The patient has not been heard of since.

CASE 2.—The subject of this case was a middle-aged man, who was seen in September, 1879. There was a round tumor in the epigastric region, extending down to the umbilicus, and apparently connected with the liver. It was particularly prominent in the very centre of the epigastric region, and there was indistinct fluctuation. The tumor was very tense, and pressure gave rise to very great discomfort, but not amounting to acute pain. The tumor did not extend much to either side, and this made the diagnosis a little puzzling; but, taking everything into consideration, it seemed certain that it was a case of hydatid of the left lobe of the liver. The patient lived a long way from the hospital, and he could not go there. Mr. Downes, then and there, in the open fields,

surrounded by an interested group of villagers, inserted a small trocar and canula, and drew off more than a quart of fluid, which was slightly turbid. This gave marvellous relief immediately. The man was carried to his cottage and kept quiet for some weeks.

After about a month or six weeks, he paid a visit to the hospital. He was not then suffering from any pain or inconvenience, but a small tumor, apparently containing fluid, was in the position of the original tumor. As in the former case, this reaccumulation of fluid was not tapped, and the patient was told that this swelling would probably subside of itself. He did not present himself again, so that it is hoped that he considered himself cured.

These two cases illustrate what has already been written by the late Dr. Murchison—viz., that hydatid tumors of the liver may be tapped in the majority of instances with a small trocar and canula without danger; and that this proceeding gives immediate and complete relief, and in many cases may cure the disease.

Rabies.

The following opinions concerning rabies we take from the *Lancet*, December 30, 1882:

At a recent meeting of the Académie de Médecine, M. Bouley communicated, in the name of M. Pasteur, a series of conclusions regarding rabies at which the distinguished investigator has arrived. The first two enunciate the familiar truths that the dumb madness and furious madness, and, in short, all varieties of rabies, are caused by the same virus, and that the symptoms of rabies are extremely variable. It is assumed that the characters of the several cases depend on the points in the nervous system at which the effect of the virus is chiefly localized. In the saliva of rabid animals the virus is associated with several kinds of organisms, and the inoculation of the saliva may cause death in three ways: by means of the special salivary organisms, by excessive suppuration, and by rabies. The medulla oblongata of the human subject, as well as that of animals, after death by rabies, is always virulent, and the virus is also found in all parts of the brain, and it persists even after putrefaction has set in. There are two methods of inoculation by which the period of incubation of rabies may be greatly shortened, and the disease produced not only rapidly but with certainty: one is by the injection of the virus into the blood; the other is by trephining the skull and placing the virus in the arachnoid cavity. Rabies then comes on at the end of six, eight, or ten days. M. Pasteur has met with some cases of the "spontaneous cure" of rabies, but only in cases in which the disease did not develop beyond the initial stage. In such a case, in which the early symptoms passed away, the disease has been known to return at the end of a certain time—as two months—and then to run the ordinary acute and fatal course. Mention is also made of the cases of three dogs inoculated in 1881: two quickly died from rabies; the third, after manifesting the early symptoms, recovered. The latter animal was inoculated by trephining in 1882 on two separate occasions, but without effect. M. Pasteur asserts that he now possesses four

dogs which will not contract rabies, whatever the method of inoculation adopted or the proved virulence of the material employed. These facts he believes to be the first step towards the discovery of a method of the prevention of rabies by its inoculation. He confesses, however, that the end seems to be at present far distant.

True Eastern Leprosy Treated by Chaulmoogra Oil.

James Startin records the following case in the *Lancet*:

The patient, who has been in England now for four years, had traces of the disease, he states, about sixteen or seventeen years ago, and about twelve months since got very much worse—a formation of tubercles and ulcers taking place, which would not heal under all ordinary treatment. For the previous eight years, the patient stated, he had lived a very hard life in Africa (Southern) among the diamond-fields, digging and washing diamonds; and whilst there he was exposed to great heat in the day, and damp, cold, and miasma at night; he could get no fresh vegetables, and, indeed, hardly any food sometimes, and that of an indifferent character. Previous to his living in the diamond-fields, he was exposed to much privation on the sea. Sometimes he stayed in port in India, sometimes in the West Indies at Demerara, and had at times very bad food. He had also resided twenty years ago in Rio Janeiro; and—in my opinion a most important element in this history—he had a very bad attack of ague twelve years ago, relapses of which he has had several times since, some being worse than others. The patient is a short, thick-set, short-necked man, with sallow complexion and curvature of the spine in the upper part of the column. He is about forty-five years of age. He now has many small hard tubercles in different parts of his body, more especially on the hands and feet, on the dorsal surfaces, on the shoulders, legs, and thighs, face and ears, with also the remains of an eruption of macule, brownish in tint. These tubercles are hard and nodular to the touch, and nearly all suppurating. The ulnar and peroneal nerves are much thickened and tender to the touch. There is slight wasting of the muscles of the thumb and interossei; the sight is getting weak, and there is slight opacity of the left cornea, and he complains of great loss of muscular power; he has lost sexual power, and has a feeling of numbness and of pricking sensation in the hands and feet, along with fits of depression. All these symptoms go to show the true character of the disease. He has little or no loss of sensation in his body, in any of the patches or otherwise, like the case I reported to you in 1880.

After many applications both of specific and other kinds had been made to this case, with little or no benefit to the patient, Dr. Corbett consulted me as to the nature of the case and its treatment. We came to the conclusion that it was a case of true Eastern leprosy in its early stages, and we resolved to give the patient chaulmoogra oil, both internally and externally. He was ordered three capsules of oil three times a day, and the crude oil to be rubbed into the parts well whenever affected twice a day. From the time this treatment was adopted the patient im-

proved, and on July 4th Dr. Corbett writes to say: "I do not think I can add much to the history of the case or its description, except to supply the omission, that the tubercles, after suppuration, left deep ulcers with sharply defined edges and smooth sores, which no treatment, tonic or alterative, seemed to heal until the chaulmoogra oil was taken, when in a few weeks reparative action was set up, and they all quite healed. Fresh tubercles, not many in number, and entirely confined to the dorsum of the hands and feet, including the fingers and toes, still form and suppurate, but not one has resulted in ulceration. Since the oil has been taken, in fact, a good many of the tubercles do not suppurate, become abortive, and die away."

Now this case, as well as the last I reported to you, were much benefited by the administration of chaulmoogra oil; in fact, the case I reported in October, 1880, is as nearly well as can be, and the man is able to resume all his duties. I saw this patient last week at Kingston, and he assured me he was much better, and he had very few tubercles left. In my opinion, leprosy can be relieved, if not cured; and this opinion is shared now by other members of the profession. Mr. Hutchinson states he has seen cases that have quite recovered.

Rape During Hypnotic Slumber.

From the *Obstetric Gazette* we note that Dr. Ladame, of Neuchatel, publishes in the *Annale d'Hygiene Publique* a very interesting report upon a medico-legal question. At the close of some entertainments in mesmerism given at his canton, the young people were possessed by a magnetic fever. One of the consequences of this was that a young girl became enceinte, and declared that being alone Christmas eve with a young man, who was in the habit of magnetizing her, he had violated her after having put her to sleep. The affair was submitted to a justice, and Dr. Ladame appointed to make a medico-legal report bearing principally upon the following questions:

- (1) The story of the plaintiff, ought it to be considered probable as a whole?
- (2) Could coition take place without her consciousness of the fact at the time?
- (3) Was her will so paralyzed that she was unable to offer any resistance?
- (4) Is conception possible in a state of absolute insensibility?

Dr. Ladame remarks that this is a new question in legal medicine, there existing but four cases in medical literature, dating from 1858.

Making observations on the possibility of simulation, MM. Devergie, Tardieu and Bronardel arrived at the conclusion that a girl could be violated while her will was abolished in a nervous or hypnotic sleep. Passing in review her story that she was awakened at a certain time, and again put to sleep without being able to resist, Dr. Ladame concludes there is nothing in this contradictory to the phenomena of hypnotic slumber. That coition could have taken place without her knowledge is not to be doubted, as she could have been rendered absolutely insensible. The third question is more difficult: Was her will so completely paralyzed that she could offer no resistance? It may, however, be answered affirmatively; for in

furnishing his subject with an appropriate theme of hallucination, a skillful operator could, with certain persons, provoke actions en rapport with the dream developing in their over-excited imaginations. It would seem then that the operator has really the power to direct according to his inclination the will of the subject, while in reality he directs only a hallucination; but the subject is none the less at his mercy. It remains to know if conception is possible when the woman is in a state of complete insensibility. Every author admits that the sole condition necessary to fecundation is the meeting of the semen and the ovum in the female.

The magnetizer proved an alibi, and the case was dismissed.

Medullary Sarcoma of the Eye.

Before a recent meeting of the Dublin Pathological Society (*Dublin Med. Jour.*), Mr. Ormsby showed an interesting specimen of medullary sarcoma, which was removed by him from the right orbit of a child, aged three years. The history of the case is as follows:

P. C., aged three years, from Ardfert, county Kerry, was admitted to the Meath Hospital on the 10th of March, 1882, under my care, suffering from a large tumor, about three inches long, projecting outwards from the right orbit. The tumor, apparently, had its origin in an attack of catarrhal ophthalmia about a week before last Christmas. From that time the eye swelled and the tumor grew rapidly, destroying the sight of the eye in a very short time. So quickly did the tumor grow, that the increase in size was noticed from day to day. He never seemed to suffer much pain, but wasted rapidly, having previously been very healthy and robust.

On his admission to hospital the child was weak, pale, and debilitated. The tumor was red, and had a most malignant aspect; when touched or rubbed roughly, it bled profusely from its summit; the bleeding had to be restrained by the application of styptics.

I performed the operation on the 15th of March, having determined to extirpate the growth, together with the whole contents of the affected orbit. I began by cutting the superficial structures with a curved blunt-pointed scissors, so as to separate the tumor from the upper and lower lids, to which it was found to be intimately attached. Having done this, I divided the deeper structures, and completely cleared out the whole contents of the orbit. Portions of the tumor broke down by the pressure of the finger, and some smart hemorrhage occurred. The optic nerve appeared to be attached to the posterior part of the tumor, which I ligatured and divided in front of the ligature. I then gently plugged the orbit with strips of lint steeped in cold water. After the growth was removed, it was remarkable how little hemorrhage followed; and up to the present the child has been doing very well. I consider the tumor is a malignant one, belonging to that form of disease usually called *Medullary Sarcoma*, or *Fungus Hæmatodes*. I am afraid the tumor may return; but still I thought it my duty to give the child a chance by removing this remarkable, and, in my opinion, malignant growth. Mr. Benson, Surgeon

to St. Mark's Ophthalmic Hospital, also saw the case. I also present for inspection two photographs, which were taken before the tumor was removed, and they depict very well the size and appearance this very unsightly growth gave to the little patient.

Mr. Benson remarked that a curious feature in the case seemed to be the complete adhesion that existed between the lids and the globe of the eye. It was continuous with the surface of the cornea, which was quite carneous. The tumor began as an intra-ocular one.

Is Tuberculosis a Parasitic Disease?

This question has not yet been answered, but experimental data, so far furnished, will be of service to the medical profession in settling the question.

The following are the results of some of the investigations of George M. Sternberg, M. D., as given in the *Medical News*, Dec. 30, 1882.

(a) The bacillus described by Koch, has been found in the sputa of phthisical patients in San Francisco.

(b) That this bacillus differs from the micro-organisms found in normal human saliva and in bronchitic sputa, is proved by the color-test (Ehrlich's) and by culture-experiments (see below, *i* and *g*).

(c) Tuberculosis in animals may result from inoculation—subcutaneous—with the sputa of tuberculous patients.

(d) But in several of the animals experimented upon, no evidence of tubercular deposit was found, and in others it was very slight. Total number of animals experimented upon, twelve rabbits, two guinea-pigs, and two dogs.

(e) In the animals successfully inoculated, the enlarged tuberculous lymphatic glands in the vicinity of the point of inoculation, and tubercular nodules in the lungs and elsewhere, usually contained the bacilli of Koch.

(f) But this was not invariably the case. At least a careful search failed to demonstrate the presence of this bacillus in tubercles found in the lungs of three rabbits.

(g) The bacillus of Koch was found in abundance in the tubercular nodules from a freshly-cut section of human lung.

(h) But in a similar specimen from another case, repeated examination failed to demonstrate the presence of the bacillus.

(i) Culture-experiments have demonstrated that the bacillus in question multiplies upon the surface of sterilized and jellied blood-serum, prepared in the manner described by Koch.

(j) But in the writer's experiments the bacilli have not penetrated the culture-medium, or extended upon its surface to such an extent as to indicate that multiplication was at the expense of this jellied blood-serum, which has seemed rather to serve as a *moist*, supporting surface; multiplication has apparently been at the expense of the tubercular material introduced for the purpose of inoculating this culture-medium.

The bacilli were not abundant in this material when it was first obtained from the lungs, or from an enlarged lymphatic gland of a rabbit recently

killed; but after remaining in the culture-tube for a fortnight the bacilli were found in enormous numbers, while the cellular elements of the tuberculous material had to a great extent disappeared.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—In a reprint from the *Atlantic Medical Register*, Dr. Nathan Bozeman, of New York, gives the results of his observations on the value of graduated pressure in the treatment of diseases of the vagina, uterus, ovaries and other appendages. The pamphlet is neatly printed and illustrated, and the importance of the facts it contains makes it well worth the perusal of gynecologists.

—The annual report of the State Hospital for the Insane at Norristown, Pa., indicates that that institution is under excellent management. The secret of success, says the report, in the treatment of the insane is embraced in two words—employment and non-restraint.

—An interesting study by Dr. Charles K. Mills, of this city, on hystero-epilepsy, will not fail to attract those who have paid attention to this strange disease. It is a reprint from the *Journal of Nervous and Mental Diseases*. With regard to the differential diagnosis, the following extract is in point:

In the epileptoid varieties of hystero-epilepsy, either the loss of consciousness is manifestly complete, the patient not responding to any outside irritants or influences; or we have a condition of what might, perhaps, best be termed altered or perverted consciousness, where it is hard to determine whether the patient is totally oblivious to her surroundings. While, however, loss of consciousness is sometimes to all intents and purposes complete in hystero-epilepsy, the careful clinical observer will not fail to notice a difference in the appearance presented by the patient and that exhibited in the paroxysm of grave epilepsy.

—The *Bromide of Ethyl* is very highly praised by Dr. J. J. Chisholm, as the most perfect anæsthetic for short, painful, surgical operations. In a reprint from the *Maryland Medical Journal*, he says of it:

Those who will use it by a single inhalation, to produce a short, deep sleep, and not resort to a mal-administration of this very valuable, powerful agent for a continued anæsthesia, which it is incapable of sustaining in safety and in comfort, will become as enthusiastic as I am over its brilliant results. They will in time learn to consider it, as I do, the most perfect of anæsthetic agents for quick, painful surgical work.

—A long and thorough article, reprinted from the *Virginia Medical Monthly*, has appeared from the pen of Dr. James L. Cabell, on "Sanitary Conditions in Surgery." We state the result of his study in his own words:

Let us, then, conclude that Listerism, in connection with amputations, if not always and everywhere necessary—if perfect sanitation, good nursing, and the keen and constant attention of the surgeon be provided—is yet the "safest of methods as obviating occasional unavoidable defects of hygienic management, whether in hospitals or private practice."

—The report of the Commissioner of Agriculture for 1881 and 1882 contains the results of the experiments conducted by Drs. Salmon and Detmers relative to the nature and cause of destructive diseases of domestic animals. The maladies particularly investigated are hog and fowl cholera and Southern cattle fever. Dr. Salmon describes an ingenious apparatus for the cultivation of bacteria. Dr. Lyman contributes a valuable article on the contagious pleuro-pneumonia of cattle. The report is one highly creditable to veterinary science in the United States.

—Landreth's Rural Register and Seed Catalogue is worth the attention of our country readers. It is distributed gratuitously to applicants by D. Landreth & Sons, Philadelphia.

BOOK NOTICES.

Transactions of the Medical Association of the State of Missouri, 25th annual session, 1882. St. Louis, Missouri.

In this seemly volume of 220 8vo. pages we have ample evidence of the prosperity of the Missouri Society. It contains, moreover, eighteen original articles besides the customary address, and several of these contributions indicate a high order of observation and much careful research.

The address of the President, Dr. Willis P. King, of Sedalia, on "Quacks and Quackery in Missouri," is a telling addition to the exposures of charlatanism. It is really hard to conceive the brutality, unfeeling greed, and ignorance displayed by the innumerable quacks that infest that and, alas! many other States. Here is one of the mildest examples:

From Southwest Missouri: "An old practitioner here said to me that 'Dover's powder was a favorite remedy with him, as it would produce a gentle *diaporefus* and had a soothin' effect on the *mucous membrane of the brain*.' I met another in consultation in a case of spitting blood from vicarious menstruation, and I suggested this as my view of the case. 'Yes,' said the doctor, 'the

blood is stopped in the womb and forced through the follopian tubes into the lungs.'"

Such examples would be amusing, did they not mean suffering to the innocent patient and fraud on his family.

A Manual of Histology. Edited by Thomas E. Satterthwaite, M. D. Second edition. New York, Wm. Wood & Co. 8vo., pp. 490.

Dr. Satterthwaite, in association with a number of other gentlemen, has presented the subject of histology in a series of independent essays in chapters, covering pretty much the whole ground of that field of research. As each contributor wrote on the special organ or subdivision of the subject with which he was best acquainted or most interested in, the work is of that composite character now becoming so popular, and probably justly so.

The fact that a second edition appears no long time after the first, shows that the work commends itself to the reading part of our profession. Histology, moreover, is a peculiarly attractive field to many, and this volume is an excellent introduction to it. We cannot say that it is extended enough to satisfy the devoted student of that branch. It is not. But it is an attractive exposition of the leading facts, and well suited to the wants of the ordinary practitioner.

It is very well printed, with numerous illustrations, on excellent paper, and in a clear, readable type.

Legal Medicine. By Charles Meymott Tidy, M. B., F. C. S., etc. Vol. I. and II. New York, Wm. Wood & Co.

The name of Professor Tidy is well known in England for his various researches in branches of forensic medicine and sanitary measures. He is a learned man and a lucid expounder of science. His work before us takes up the subject of medical jurisprudence in a condensed but exhaustive manner. The scheme he selects is a good one, and he carries it out with marked ability.

The work belongs in Wood's Series of Standard Medical Authors, and is one of the best of the series.

A Dictionary of Medicine, Including General Pathology, general therapeutics, hygiene, and the diseases peculiar to women and children. By various writers; edited by Richard Quain, M. D., F. R. S., New York. D. Appleton & Co., 1883. 1 vol. 8 vo. pp. 1816.

In this important work the editor has endeavored to combine two features or purposes: in the first place, to offer a dictionary of the technical words used in medicine and the collateral sciences,

and also to present a treatise on systematic medicine, in which the separate articles on diseases should be short monographs by eminent specialists in the several branches of medical and surgical science.

Especially for the latter purpose, he secured the aid of such well-known gentlemen as Charles Murchison, John Rose Cormack, Tilbury Fox, Thomas Hayden, William Aitken, Charlton Bastian, Brown-Sequard, Sir William Jenner, Erasmus Wilson, and a host of others. By their aid, he may fairly be said to have attained his object of "bringing together the latest and most complete information, in a form which would allow of ready and easy reference."

Of course, the several articles are necessarily brief, and there are instances where they are obviously too brief to do justice to the subject; but this is a welcome relief after the outrageous tediousness and diffuseness of some of the *encyclopedias* which have of late been inflicted on the long-suffering and easily-gulled American medical public.

To give an idea of the fullness of treatment, we find that the title *Cancer* is treated by Dr. R. J. Godlee, in three and a half pages (double column, small type); *Insanity* has eighteen pages; *Neuralgia*, three pages; *Phthisis*, seventeen pages; *Pyæmia*, seven pages, etc. These limits give fair space for the discussion of the essential known facts about these complaints; and as the articles are composed by persons thoroughly familiar with the subject, and trained to recognize the useful and real from the theoretical and doubtful, the text of these monographs is generally admirable for clearness and condensation.

As a dictionary of words and terms, we cannot place it on so high a plane as when we regard it as a collection of monographs. Many of the older and partly or wholly obsolete terms are not to be found in it. Yet no *dictionary* is complete without them. The etymologies are often too brief or questionable, and the synonymy in other tongues is scanty, although this is a very useful feature to the student. In these respects we place it as inferior to Dunglison's Dictionary.

The publishers have done very well in the manufacture of the book. Though it contains over 1800 pages, it is not inconveniently bulky. The type, though small, is clear, the paper clean and strong, the binding solid and firm.

There are various illustrations and some whole-page plates, all of which are satisfactory in execution, and material additions to the value of the volume.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

VENESESECTION.

Of late years this practice is being revived, and like all other reliances that have been relegated to obscurity because they have been unduly and unwisely resorted to, it will now, we have reason to hope, be placed upon a rational and substantial basis, and continue to be, as it ought, one of our most effectual therapeutic resources.

Dr. W. H. Broadbent, who contributes a very interesting paper on the subject to the *Lancet*, January 13, 1883, considers that the most striking instance of its good effects is to be found in uræmic convulsions. The indications for venesection, according to his views, are just the reverse of those usually described:

"The face is pale: when the fingers are placed lightly on the radial artery, pulsation is hardly felt, and the vessel is usually small, though it may be large. The first impression is that the pulse is weak. When pressure, however, is made so as to test the force of the current of blood, the pulsation is not easily extinguished, and the firmer the pressure, the stronger the beat seems to be. At the same time the artery is full between the beats, and can be rolled under the finger like another tendon, or like a piece of whipcord. The heart will be usually found to be hypertrophied, and more or less dilated, and very commonly there is reduplication of the first sound over the inter-ventricular septum near the apex, due, as Dr. Sibson demonstrated, to want of synchronism in the systole of the two ventricles. When with these evidences of high arterial tension, convulsions supervene, the most prompt and certain remedy is venesection."

He has found it very useful, whenever in kidney disease the symptoms of uræmic poisoning show themselves, vomiting, headache, confusion, stupor, muscular twitchings, etc., which experience has taught lead up to convulsions. He has in several cases, both of contracted granular and large white kidney, when cure was hopeless, diminished the suffering of the last few weeks of life, and changed the mode of death, by small bleedings when the headache became intolerable and convulsions were impending. If venesection will do what he claims for it, it will prove, indeed, a great boon; but we must be cautious in resorting to an expedient that is so strongly condemned by many eminent observers. At the same time, it is true that one by one the members of our profession are falling into the line of advocating modified venesection, and we cannot help

but think that reason, as well as the weight of clinical evidence, is in its favor. The great trouble with venesection, as with all other possibly dangerous remedies, arises from the fact that the majority of physicians are content to let others do their thinking for them, and to practice medicine by routine. A man who sedulously cultivates the habit of thought, will, in the majority of cases, be able to accurately determine whether the abstraction of blood will be likely to prove beneficial or the reverse.

As a general rule, when no contra-indication exists, it may be stated that venesection will probably prove beneficial in those cases wherein drastic purgatives are indicated for their depletory and counter-irritant effects, and the pulse will be your guide to the extent of venesection called for.

In puerperal convulsions, in which venesection has been highly vaunted, it is recommended to bleed to syncope, but in the other conditions it would be well to stop short of this point; to desist when the pulse indicates that the high arterial tension causing the trouble has been reduced.

ERYTHEMA GANGRÆNOSUM.

Whether there ever exists a peculiar condition of the system giving rise to gangrenous patches on different portions of the body, is a question that possesses a great deal of interest in a medico-legal sense, since the artificial production of the so-called erythema gangrænorum is a favorite practice among malingerers.

Dr. T. Colcott Fox recently read an account of two cases before the Royal Medical and Surgical Society, in which the patches were limited to the chest and arms, and occurred over and over again about the site of former patches, sometimes for a time forming only on one arm, then on the other, and then about the chest, but a sort of symmetry was often kept up. The change commences with discoloration of the epidermis, passing rapidly to the formation of a bulla and then to gangrene, the consequent sores healing very slowly. It was noticed that while not exclusively confined to, yet this condition was most frequently observed among intemperate persons.

Since any part will become gangrenous if deprived of its nourishment, and since Dr. Fayrer has concluded that thrombosis of the pulmonary artery may occur as the result of some but imperfectly-understood constitutional conditions, may we not infer by analogy, that when this cachexia (whatever it may be) exists, the circulation of the skin, in a certain area, may become so obstructed, by coagula, as to deprive the part of nourishment and to produce these gangrenous blotches?

In the discussion which ensued on this paper, Mr. Savory pointed out that the detection of the artificial use of caustics was facilitated by noting the shape of the patches, which showed greater irregularity in outline, especially of the lower margins (from the gravitation of the fluid) than is the case in patches of true skin disease.

This is an interesting field for observation.

NEW REMEDY IN DIPHTHERIA.

A German apothecary, R. Münch (Kronen-Apotheke in Leipsic-Sohlis), who enjoys a great reputation for veracity and reliability amongst those who know him, recommends in No. 27 of the Pharm. Centr. Anzeiger, "as a new remedy in diphtheria, and the effect" of which he had noticed on his own 7-year-old daughter—oleum terebinthinæ rectificatum. Children take one teaspoonful morning and night; adults, a tablespoonful. In children tepid milk is given after it; it might also be mixed with the same. The effect of this remedy, which has of late been highly praised by different authors, is said to be really a miraculous one. Within already half an hour after the administration of the drug, a bright redness begins to spread from the margin of the diphtheritic exudation, and this redness becomes generally diffused over and taking the place of the false membrane, and the disease is said to disappear within twenty-four hours without leaving the slightest trace. While this wonderful effect is said to be invariably met with when the remedy is made use of at the very commencement of the disease, those who recommend it so highly contend that it is also successful, only less rap-

idly, in cases that have already progressed for several days.

PROPHYLACTIC INFLUENCE OF TINCTURE OF IRON ON CONTAGIOUS DISEASES.

A somewhat singular, and if substantiated, very valuable observation has been made by Dr. W. Duff Green, of Mt. Vernon, Ill., in the *St. Louis Courier of Medicine*, February, 1883. He relates his experience in six families, wherein he treated typhoid fever or measles. In every individual to whom he had given tincture of the chloride of iron, if the disease appeared at all it was very slight, while the majority of those so treated escaped it altogether; at the same time nearly all of those who did not take the iron had the disease in its ordinary severe form. He has noticed this prophylactic action since 1877, and he only records a few of his many observations. It may be that the iron simply enables the system to withstand the onset of the disease, by giving it tone, without possessing any specific action; but whatever the explanation is, this report is sufficiently valuable and trustworthy to stimulate further investigation.

NOTES AND COMMENTS.

Indications for the Use of Different Kinds of Electricity.

To recognize the differential indications is one of the most difficult things in medicine. We have, says Dr. A. D. Rockwell in the *New York Medical Journal*, February 3, 1883, galvanic, faradic and franklinic, or static electricity, each one of which differs from the others in its therapeutical properties. In hemiplegia, where there exists an exalted electro-muscular contractility, electricity, if used at all, should be used in the form of faradization, and with an exceedingly mild and rapidly interrupted current. On the contrary, when there is a very great diminution of electro-muscular contractility, the galvanic current is indicated. When we wish to directly affect the central nervous system the constant current is alone applicable. As a general rule, it will be found that in neuralgia, where firm pressure over the affected nerves aggravates the pain, the galvanic current is indicated, while when the opposite condition obtains, the faradic current will

prove more useful. In what we call "*general debility*," the faradic current is indicated. Asthenopia, accompanied by hyperæsthesia of the retina and ciliary nerves, seems to demand the faradic current; as is also the case in diphtheritic paralysis. The so-called spinal irritation or spinal neuralgia calls exclusively for galvanism, as well as in sequelæ of cerebro-spinal meningitis; also will it oftentimes afford much relief in exophthalmic goitre.

For the restoration of the lost senses of taste and smell, galvanism succeeds when faradism fails. So also in skin diseases, where electricity is of service, the galvanic current is the one indicated. For herpes zoster, in electro-surgery and in the treatment of erectile tumors, galvanism reigns supreme. It is to be preferred as a fœticide in extra-uterine pregnancy. In sthenic chorea it is indicated, while in the asthenic form faradism must be used. The same rules will guide in amenorrhœa. The pain of muscular rheumatism will be relieved sooner by franklinization than by either of the others, and its use is more particularly indicated in pain confined to no special nerve trunks, dull and aching in character, and with no tenderness on pressure. Study first dynamic electricity, and then go to franklinism.

Chloral in Albuminuria.

Thomas Wilson, in the *British Medical Journal*, December 23, 1882, cites several cases showing the efficacy of chloral in the above condition; the attention of the profession does not yet seem to have been generally drawn to the effect of chloral in removing albumen from the urine, and also the existing œdema.

Mrs. R—, a delicate woman, age 40, who had just past through utero-gestation, presented albuminous urine and dropsy, orthopnœa, lips cyanosed, pulse weak, no cardiac murmur was detected. The diagnosis of dilated heart, passive congestion of kidneys, and dropsy, was made.

From the regularity with which it was noticed that the urine passed after taking chloral was clearer, of lower specific gravity, and contained less albumen than that passed at other times, it was decided to test the effect of chloral by withholding its administration altogether. No sooner was the drug stopped than all the symptoms returned. Urine passed after taking chloral was of average specific gravity of 1016, acid, with no albumen; specimens passed at other periods contained albumen and granular and hyaline tube casts.

No explanation is offered as to how the chloral

was followed by such beneficial results. "Suffice it to say, that under its use, a lady so prostrated that she could not stand, with a dilated heart, albuminuria, and marked œdema of feet and legs—indications of a grave constitutional state—has simply been rescued from death."

In another case, a woman, age 68, chloral was as successful as in the former.

No apparent diuresis or diaphoresis was produced.

Nocturnal Eneuresis, Treated by Voltaic Alternatives.

Dr. Althaus writes in the *British Medical Journal*: "In June, 1882, I was consulted in the case of a boy, aged 15, who had suffered from incontinence of urine during sleep, ever since he was nine years of age. He had been treated with belladonna and other medicines without relief; and as he was about to enter a public school, where a continuance of this trouble might have been particularly annoying, the parents were very anxious that something more should be done. The boy's general health was good, but he was considered a nervous child, and highly sensitive. There were no ascarides, but he had a very long prepuce which could only with difficulty be retracted. There was, however, no suspicion of masturbation. Treatment by electricity having been recommended, I applied the middle-sized circular cathode over the region of the bladder, and the large oblong anode (five inches by two) to the lumbar portion of the spine. The current-strength 2.50 milli-ampère for five minutes at a time. As after a few such applications no material benefit appeared to have been gained, I then added fifty voltaic alternatives produced in the metallic circuit. The night after this was free from the usual annoyance, and the boy has made an apparently uninterrupted recovery." Dr. Althaus prefers this method of treatment to injections of nitrate of silver, as recommended by Sir Henry Thompson. He believes that belladonna is of value when eneuresis is distinctly caused by undue excitability of the bladder.

Faradization of Spleen in Intermittent Fever.

The *London Medical Record*, January 15, 1883, says that Dr. Babaeff regards (*Mediz. Obozr.*, Feb., 1882) systematic faradization of the spleen as one of the best adjuvant means in the treatment of intermittent fever, and adduces some cases of his own in which the usual antiperiodic remedies had remained unsuccessful until the electricity had been added. The faradization not only dimin-

ished the splenic tumor, but also acted beneficially on the malarial process. This favorable influence the author attempts to explain as follows. 1. Faradization gives rise to contractions of the splenic vessels, and, in a reflex way, acts tonically on the vaso-motor centres. 2. It counteracts blood-stagnation, and possibly accumulation of miasmatic products in the spleen. 3. It acts indirectly on the neighboring kidney, increasing correspondingly the secretion of urine. 4. It prevents the formation of infarcts and ruptures in the spleen. The editor of the *Mediz. Obozr.*, Dr. V. F. Sprimon, also testifies to the high value of faradization and galvanization in cases of chronic malarial tumor of the spleen. He saw its prompt disappearance, as well as a great improvement of the general state, in four out of five of his patients treated by this method. In four of the eight of Dr. Sprimon's cases which presented intermittent of recent standing, and were treated by faradization alone, the fever disappeared and never returned after five to ten sittings (half an hour daily).

The Mortality Referable to Alcohol.

The *British Medical Journal* says: At the end of a long and carefully-prepared report recently drawn up by a committee of the Harveian Society, it is concluded: that there is, upon the whole, reason to think that, in the metropolis, the mortality among any considerable group of intemperate persons will differ from that generally prevailing among adults in the following important particulars, viz., a fourfold increase in the deaths from diseases of the liver and chylopoietic viscera; a twofold increase in the deaths from disease of the kidney, a decrease of half as much again in those from heart disease, a marked increase in those from pneumonia and pleurisy, a considerable increase and an earlier occurrence of those from disease of the central nervous system; a marked decrease in those from bronchitis, asthma, emphysema, and congestion of the lungs, a decrease nearly as great as in those from phthisis, and a later occurrence, or at least termination, of the disease; a very large decrease in those from old age, with an increase in those referred to atrophy, debility, etc., and the addition of a considerable group referred in general terms to alcoholism or chronic alcoholism, or resulting from accidents.

Atmospheric Pressure and Apoplexy.

At certain seasons of the year, or rather at special times, apoplexy seems to be almost epidemic. Dr. Bürger, physician of the county Gerabronn,

in Wurtemberg, studied the relation atmospheric conditions seem to have to apoplexy. From 1877 to 1879, inclusive, 78 persons died in the county of this disease, and Bürger found that the atmospheric pressure was decreased on the days such attacks happened three times oftener (in 53 cases) than increased (in 19 cases). It is a pity that the different forms of the malady had not been classified, or it might have been found that serous apoplexy, the form we mainly find in diffused kidney lesions, happens especially when the atmospheric pressure is lowered, while in apoplexy due to congestion or in the hemorrhagic form the opposite holds good, and a stroke of paralysis due to embolism will not be in any way related to changes in the atmospheric pressure. But the want of this information shows again the necessity which we have so frequently urged upon our medical confrères of being as accurate as possible in the statement of the cause of death, or death certificates. By such statements being made more accurate, many more valuable facts could be gained for science from statistical tables taken from the records of death-rates.

Pyrogallic Acid in Phagedæna.

From the *Union Medicale*, January 4, 1883, we learn that M. Vidal, Surgeon to the St. Louis, thus concludes a paper which he read at the Académie de Médecine, "On the Treatment of Phagedæna of Simple Chancre by Pyrogallic Acid or Pyrogallol": 1. By destroying the virulence of simple chancre, it arrests phagedænis and rapidly transforms it into an ordinary sore. 2. Only causing very slight pain for some minutes, limiting its caustic action almost exclusively to the diseased tissues, and easy of application to all the invaded parts, pyrogallol, incorporated with an ointment mixed with an inert powder in the proportion of one-fifth, has proved to be the best topical application to simple chancre and phagedæna. 3. It may be applied over large phagedænic ulcerations without danger accruing from its absorption. 4. Although so remarkable in its efficacy in the phagedænis of simple (invading) chancre, it has no special action on the phagedænis of syphilitic ulcerations (tertiary phagedænis).

Micrococcus Puerperalis.

The *Medical Record*, February 3, 1883, says: Recently pathological investigation has pointed very strongly toward the conclusion that a micro-organism is the cause of puerperal septicæmia. We are quite prepared, therefore, for the an-

nouncement that M. Chauveau has isolated this organism, cultivated it, attenuated it, and used the attenuation as a vaccine.

M. Chauveau experimented with rabbits, and states that he produced in them the lesions and symptoms of puerperal fever. His experiments as to the protective power of attenuated virus are not yet completed. But he states that those rabbits which survive the first inoculations are not susceptible to any subsequent attacks, even when virulent virus is injected.

The profession will wait with much interest for the conclusion of Chauveau's experiments.

The Action of Thymol on the Circulation.

The *London Med. Record*, January 15, 1883, says that Dr. Fiori used thymol in fever and apyrexia, with heart sound or diseased, taking observations of the temperature, pulse, respiration, blood-pressure, in doses from $\frac{1}{2}$ gramme to 5 grammes. The observations were taken every quarter of an hour. Sixteen individuals were experimented on. He concludes that thymol produces rapid and considerable fall of temperature and diminution of the frequency of the pulse in fever. In healthy persons also it retards the pulse. In the sphygmographic tracings is seen in most cases a tendency to rounding of the curves, and at the bifurcation of the apex of the curve a greater accentuation of the oscillations of elasticity. With the fall of temperature, the blood-pressure diminishes. Thymol, while it lowers the temperature, has no bad effect on the heart; and can therefore be considered a true antipyretic remedy.

Nephrectomy.

In the *Dublin Jour. of Med. Science* for January, 1883, Mr. Stokes relates another unsuccessful nephrectomy performed by Mr. Francis J. O'Reilly. The right kidney was removed from a patient aged 26, suffering from right kidney symptoms and pus in the urine. A favorable opinion was formed of the ability of the left kidney to take on the action of both. The operation was by the vertical lumbar or post-peritoneal method, and was performed antiseptically. The vomiting and depression manifested during the operation continued, and the girl died in 48 hours.

Purgatives for Hypodermic Use.

The *Boston Med. and Surg. Jour.*, February 3, 1883, says that Dr. A. Hiller, of Berlin (in *Zeitschrift für klin. Med.*, Bd., iv.), reviews the various cathartics that have been recommended for hypodermic use, and concludes that none of them is

at once reliable and free from objections. Aloin is uncertain in its action, and has been given in doses of 0.8 without effect, and citrullin (from the colocynth), cathartinic acid (from senna), elaterin, euonymin, baptisin, etc., are all found to be either ineffective in moderate doses, or to cause great pain and local inflammation. So that the writer concludes that pharmaceutical research is still inadequate for the solution of this problem, which, however, he believes will some time be solved.

Left-Side Pain.

We frequently have patients come to us complaining of pain in the left side, who are otherwise apparently healthy, and we are at a loss to account for the pain. At a recent meeting of the Academy of Medicine, in Ireland, Dr. Wallace Beatty read a paper on this subject, which we read in the *Medical Press and Circular*, January 3, 1883. He considers the pain, in many instances, due to fecal accumulation, and it can be removed by getting rid of the accumulation. The pain is felt over the lower few ribs on the left side, associated with great pain on upward pressure of these ribs, but no pain on downward pressure. He ascribes the pain to the dragging of a loaded colon on the pleuro-colic ligament, setting up extreme irritability of the nerves.

Death from Petroleum by Suffocation.

During the night from September 18 to 19, 1882, twelve young girls died in the institution Cavalier Maggiore in Piedmont the death of suffocation, because they had permitted a kerosene lamp to burn during the night, after they had turned it half down. The flame evidently communicated itself to the fluid in the lamp, and gradually abstracted all oxygen from the room, which fact was the cause of the suffocation. The dead bodies showed all the signs of death by suffocation.

Iodoform for *Ascaris Lumbricoides*.

The St. Petersburg *Med. Woch.*, December 30, 1882, says that Dr. Schildowsky has employed iodoform successfully in three cases of ascari, and recommends that a further trial should be given of the remedy. He gives to an adult one grain with ten grains of bicarbonate of soda three times a day, and a quarter of a grain to a child.

Acute Addison's Disease.

Dr. Goodhart, of London, recently presented a dissection of the changes in the abdominal sympathetic and supra-renal capsules in a case of Addison's disease. The patient had died from

sickness, which had been supposed to be merely sea-sickness, as he was not known to have been ill previously. There was no bronzing, and the capsules were very large, and therefore, probably, the disease was quite recent.

Subnitrate of Bismuth for *Cancrum Oris*.

Dr. C. J. Maguire contributes an article on this subject to the *Medical Record*, February 3, 1883. He has had under his personal care twenty-four cases, of which he has lost four, all before he commenced the use of the bismuth. He gives the drug internally, and considers it a specific for *cancrum oris*.

To Disguise the Odor of Iodoform.

The *Journal de Therapeutique* says that Dr. Yvon effects the abolition of the smell of iodoform by the very simple procedure of incorporating with it a little essence of roses. Half a drop of the essence removes the odor of sixty grammes of iodoform, the compound retaining that of the essence.

CORRESPONDENCE.

The Personal Experience of an Opium Habitue.

EDS. MED. AND SURG. REPORTER:—

Having had frequent attacks of sick headache, I resorted to various remedies, but without radical relief.

Five years ago I began the use of morphia and atropia hypodermically, with almost immediate success. For two years I used it whenever I experienced a recurrence of my headache, and at the end of this time resorted to it daily. The atropia acting unpleasantly, it was abandoned and the morphia continued, gradually increasing the frequency and amount of the injections, until at the end of three years, I could take with impunity from 12 to 15 grains daily, although my usual quantity was about eight grains per diem.

The early effect of my addiction was very agreeable, enabling me to endure more work, mental and physical. But, after increasing the daily quantity above one or two grains, it produced great prostration, and occasionally severe attacks of vomiting, which usually continued from three to six hours.

I made frequent attempts at self-abandonment, but always failed, and I think it almost impossible to secure such a result without assistance.

Finally, after being miserable for nearly three years, I endeavored to seek aid from some one giving special attention to the treatment of this disease, and accordingly consulted a gentleman well known to the readers of this journal, and soon placed myself in his care. To my astonishment I was cured in less than three weeks, the morphia being withdrawn in one week, without any discomfort whatever; and twelve days later, I

returned home without having lost an entire night's rest. It is remarkable that after the nervous system has been accustomed to opium for years, one can be relieved in so short a time by appropriate treatment.

It will give me pleasure to correspond with any medical gentleman who may be in the bondage from which I happily have escaped.

D. W. BASHORE, M. D.

West Fairview, Pa.

Salicylic Acid and Acute Rheumatism.

EDS. MED. AND SURG. REPORTER:—

I had recently under my care a strong man with a syphilitic taint, who came complaining of swelling and excruciating pain in his hand. The skin was brawny, there was a dry, pungent heat, and, indeed, the case presented every evidence of commencing acute inflammatory rheumatism. It had commenced two days before in one finger, had gradually involved the hand, and was commencing to affect the wrist. Knowing that my patient could take medicine well, I gave him twenty grains of salicylic acid (without any excipient, pure and simple) every two hours, until he had taken one hundred and eighty grains. After the second dose, he experienced relief, and when the full quantity was consumed, he needed no more medication, having complete use of his hand within three days. Since some authorities claim that salicylic acid may be dangerous, I would utter a caution against such large doses unless you can have your patient under close observation; though I have now used it in several cases, and have never seen an untoward effect.

Texas.

I. BROWN, M. D.

Large Doses of Copperas.

EDS. MED. AND SURG. REPORTER:—

Two or three weeks ago I was called to see a mother and child who had taken a dose of salts "that had worked the wrong way." On seeing the patients, I learned that during the previous night at 11 p. m., the mother had taken one teaspoonful and a half of copperas (pulverized) instead of salts, which produced violent emesis, with severe pain in her stomach, which disappeared in an hour or two. Not ascribing the reversed action to the "salts," she repeated the dose the following day at 11 a. m., giving her little boy about the same quantity in a hot water solution. The effect in the case of the mother was a repetition of that of the former dose, except that it stimulated her memory to a recollection of the fact that she had taken copperas instead of salts, and that she had mistaken the paper containing the salts. In the case of the little boy the effects were not so slight. It did not act as an emetic, but produced great depression, followed by coma, and at that time, four hours after taking the dose, the patient could only be temporarily aroused. Something had to be done. Not having a chemical antidote at hand, I concluded to give him an emetic dose of ipecac, which produced emesis, followed by return of consciousness. I now gave him milk and eggs with opium, to relieve pain in his stomach. Mother and child made a good recovery in two days.

Cherrytree, Pa.

J. U. BLOSE, M. D.

Lime in Croup—Sulphur in Diphtheria.

EDS. MED. AND SURG. REPORTER:—

In reading a communication from a correspondent in last week's REPORTER in reference to the treatment of croup by lime inhalations, I was reminded of many cases I had treated in this way years ago with marked success. My attention was first called to this mode of treatment by seeing a notice of it in Vol. XIII. of this journal, 1865, page 171. Those that may feel an interest will do well to refer to the above number of the REPORTER. I will quote a few sentences. After stating that a German by the name of M. Kuchenmeister had found that "diphtheritic membranes are rapidly dissolved in lime water," the *British Foreign Medical and Chirurgical Review* says that some pseudo-membranous exudations of considerable extent and thickness were placed in a small glass of lime water, and in the space of from ten to fifteen minutes they disappeared, leaving only a very slight sediment at the bottom of the glass. It having been my lot heretofore to have been called to many cases of croup, many of which had run on rapidly to a fatal termination, I was therefore particularly anxious to find a remedy that would resist the great fatality of this disease. Since adopting the lime inhalation treatment my success has been almost uniform. But the lime inhalations will only answer where the deposit is that of true croup. In the croupous form of diphtheria, or diphtheritic croup, it has no effect whatever, as many trials of it, at different times, have fully satisfied me. But like lime in the treatment of croup, so sulphurous acid and sublimed sulphur seemed to be the most reliable remedies in removing the deposit of diphtheria. Sublimed sulphur, as it comes to us, is always acid, and if we expose it to the air for a time it becomes still more so. This, blown into the fauces, or placed dry upon the tongue, I have seen remove the membrane in a very short time. So it would seem that an acid was indicated in the treatment of diphtheria, while alkali was indicated in the treatment of croup. That the deposit of croup and that of diphtheria are widely different, I am fully satisfied. The croupous form of diphtheria often so simulates true croup that at times a correct diagnosis becomes difficult. But it is very necessary that an early discrimination should be made, as much valuable time may be lost in letting these formidable complaints run on their natural course.

In the spring of 1857, several cases of membranous croup occurred in my circuit. Those that were seen early, it was found that small and repeated doses of calomel was the most reliable remedy, but the case had to be seen early. Two cases proved fatal in one family in the spring of that year. With the assistance of Dr. S., then of Mt. Holly, I removed a section of the trachea of one of these fatal cases. We found the trachea so filled with deposit that a knitting-needle would scarce pass through. The specimen was exhibited at a meeting of our Medical Society, and elicited much interest. It finally passed out of my hands, and I think was placed in the museum of the Jefferson College. None of these cases, I think, had any deposit in the fauces, or above the epiglottis.

WM. L. MARTIN, M. D.

Rancocas, N. J., January 26, 1883.

NEWS AND MISCELLANY.

The Lamson Life Insurance.

The case of Dr. Lamson, whose crime and execution in England we have recorded, has had a queer termination. The murderer had a life insurance of \$5,000, payable to his widow. Immediately after his execution, claim was entered for its payment. The company objected on the ground that the assured had died neither from natural causes, disease, nor unavoidable accident. The estate claimed, however, that though the death was a violent one, it was in no sense like a suicide, which would, of course, have annulled the policy. The assured had certainly not voluntarily delivered himself to the executioner; on the contrary, it could be maintained that he had yielded only with reluctance. The company paid the claim under a formal protest.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine Hospital Service, Oct. 1 to Dec. 31, 1882.

Bailhache, P. A., surgeon. Present detail continued until further orders, Oct. 6, 1882. To proceed to Louisville, Ky., as inspector, Oct. 13, 1882. Granted leave of absence for thirty days, Nov. 10, 1882.

Vansant, John, surgeon. Granted leave of absence for twenty days, Nov. 18, 1882.

Hutton, W. H. H., surgeon. To proceed to Louisville, Ky., and assume charge of the service, Oct. 7 and 14, 1882.

Miller, T. W., surgeon. To continue at present station until further orders, Oct. 6, 1882.

Wyman, Walter. To inspect keepers and crews of the Life Saving Service, Oct. 5, 1882.

Long, W. A., surgeon. To proceed to Detroit, Mich., and assume charge of the service, Oct. 7 and 14, 1882.

Murray, R. D., Surgeon. Having returned from service in the yellow fever epidemic in Texas, to report in person to the Surgeon General, M. H. S., Dec. 4, 1882. Granted leave of absence until Feb. 28, 1883, Dec. 19, 1882.

Fessenden, C. S. D., surgeon. To proceed to St. Louis, Mo., and assume charge of the service, Oct. 7, 1882.

Purviance, George, surgeon. To inspect keepers and crews of the Life Saving Service, Oct. 21, 1882.

Sawtelle, H. W., surgeon. To proceed to New York, N. Y., and assume charge of the service, Oct. 7, 1882.

Austin, H. W., surgeon. To inspect keepers and crews of the Life Saving Service, Oct. 5, 1882.

Fisher, J. C., passed assistant surgeon. Present detail continued until further orders, Oct. 6, 1882. To proceed to Alexandria, Va., as inspector, Oct. 21, 1882.

Heath, W. H., passed assistant surgeon. Granted leave of absence for fourteen days, Dec. 28, 1882.

Porter, F. D., passed assistant surgeon. To inspect keepers and crews of the Life Saving Service, Oct. 5, 1882. To proceed to Evansville, Ind., for temporary duty, Nov. 21, 1882. To proceed to Charleston, S. C., and assume charge of the service, Dec. 21, 1882.

O'Connor, F. J., assistant surgeon. To proceed

to Norfolk, Va., for temporary duty, Oct. 14, 1882. To rejoin his station (Detroit), Nov. 4, 1882.

Wheeler, W. A., assistant surgeon. Relieved of duty at Charleston, S. C., and placed on waiting orders, Dec. 22, 1882.

Armstrong, S. T., assistant surgeon. To examine keepers and crews of the Life Saving Service, Oct. 5, 1882.

Bennett, P. H., assistant surgeon. To examine keepers and crews of the Life Saving Service, Oct. 5, 1882.

Ames, R. P. M., assistant surgeon. Granted leave of absence for twenty-one days, Nov. 23, 1882.

Devan, S. C., assistant surgeon. To examine keepers and crews of the Life Saving Service, Oct. 13, 1882. To inspect unserviceable property at the San Francisco Marine Hospital, Oct. 20, 1882.

Kalloch, P. C., assistant surgeon. To inspect keepers and crews of the Life Saving Service, Oct. 5, 1882.

Human Automatism.

In the course of a lecture on this subject by Dr. W. B. Carpenter, published in the *New York Medical Jour.*, February 3, 1883, he relates the following incident:

When Professor of Chemistry at Oxford, Sir Benjamin Brodie was experimenting upon a peculiarly explosive fluid of his own discovery, and was holding a small bottle of this fluid between his eyes and the light. Either through the tremulous motion or the warmth of his hand, the fluid exploded with such violence as to blow to pieces—to dust, in fact—the bottle which contained it; and his first thought was, "I am blinded; this glass has been driven into my eyes, and I shall never see again!" Upon putting his hand to his eyes, however, he found that the glass had gone entirely into the *outside* of his lids, and that his eyes were perfectly safe. Either the flash of light or the explosion (which occurred first I do not know) had called forth an instantaneous respondent muscular movement, which protected his eyes by the closure of his eyelids.

Last Year's Medical Publications.

Messrs. Sampson Low & Co., of London, announce in their *Publisher's Circular* that during 1882 there were 119 new works and 58 new editions of books on medicine and surgery and associated subjects published in England. In the year preceding, the numbers were 108 and 56 respectively. How few are worthy of publication!

The Coldest Town in the World.

The coldest inhabited town in the world is, according to *L'Union Médicale*, not Irkutsk, as has been formerly believed, but Verchojansk, in Siberia. In this place the mean temperature during the month of January was -43°F. , in February, -56°F. , in March, -37°F. Once the thermometer recorded -81.4°F.

To Powder Boracic Acid.

This acid, which it is very difficult to reduce to powder, may be finely pulverized by the following process: First warm a Wedgwood mortar by pour-

ing into it a little alcohol, and setting fire to it. Then put into the warm mortar the boracic acid, with a few drops of glycerine, when it will be found to be easily reduced to as fine a powder as desired.

The Kentucky State Medical Society.

The Kentucky State Medical Society will meet in Louisville in April, under the presidency of Dr. A. D. Price. Dr. Coleman Rogers is chairman of the Committee of Arrangements.

Longevity of Occupations.

The *Scientific American* states that the longest lived men are merchants, and then in the order named: Weavers, shoemakers, carpenters, blacksmiths, laborers, miners, tailors, bakers, butchers, liquor dealers. The mortality among liquor dealers is so great that in good companies they are admitted with great caution and on short policies. The callings of brewer, it is added, typesetter, tinsmith, lithographer and stonecutter are all unfavorable to longevity. These deductions are made from data found in the office of the Registrar-General of Great Britain.

The Death Rate of Scotland.

The Registrar-General's returns for the week ending with the 23d of December show a great contrast in the respective death rates of Edinburgh and Glasgow. The rate in the former is 21 per 1,000 per annum, and in the latter no less than 37. The average for the chief towns is 28. Our informant, the *Medical Press and Circular*, does not account for this enormous difference. It would be exceedingly interesting, from a sanitary standpoint, to know the causes.

Sanitation in the Fiji Islands.

The Fiji Government has published a special number of a native journal, *Na Mata*, which they issue from time to time, to acquaint the native population with the actual sanitary condition of the islands. During the year 1881 there was an increase of births over deaths of 204. The statistics are of a detailed character. The attention of the natives is called to the excessive mortality which still exists among the children, and much useful advice is given to parents. In districts where this advice has been acted on, the increase in the population has been most striking.

A Movement Against Vivisection.

The report of the Women's Philadelphia Branch of the Society for the Prevention of Cruelty to Animals, read at the annual meeting recently, stated that the movement against vivisection is to take a more tangible form than heretofore. Arrangements are on foot for holding a public meeting in the latter part of February, and for taking at that meeting the initial steps toward the formation of an Anti-Vivisection Society in Philadelphia. Other means will also be considered for the suppression of vivisection, "that deadliest of all cruelties."

Meanwhile, the thousands of sick men and women who could be relieved by an application of

the results obtained by vivisection are to be left to die or suffer the tortures of disease.

This is the class of people who strain at a gnat and swallow a camel.

Deaths by Violence in Russia.

Deaths by violence seem to be very frequent in Russia, the total for the last four years being no less than 164,436, of whom 129,328 were men, and 35,108 women, the proportion of the former to the latter being as 79 to 21. Out of the total of violent deaths, 11,655 were murders, 8,613 suicides, 44,418 sudden deaths, 22,529 were attributed to the effects of drink, 1,270 were due to lightning, 11,251 persons were run over, 3,936 were burnt to death, 3,326 were suffocated, 5,144 were frozen to death, 31,511 were drowned, 364 were devoured by wild animals, and 19,409 were killed in various other ways.

The Philadelphia Hospital.

A Committee on the Medical Board of the Philadelphia Hospital has sent to the Board of Guardians of the Poor an endorsement of the petition to Councils that the Almshouse be removed and the present buildings be devoted entirely to a General Municipal Hospital. The Board is earnestly advised of the importance of drawing a distinction between the sick poor and indigent paupers, and the necessity of providing for contagious diseases other than small-pox within the precincts of such a hospital by the establishment of secluded and remote wards for the reception of persons so afflicted.

Overworked Railway Officials.

The *Lancet* says that overwork of the railway officials seems likely to have been the chief cause of the collision at Cowlares Junction, in Scotland, on the 16th of December. The men in charge of one of the trains had been on duty for seventeen hours and a half; those of the other for nearly seventeen hours. Some means must be found of ensuring that good dividends are not made at the expense of public safety. Let us look to it that we are not making the same mistake.

Fire Escapes.

If the care of health means the preservation of life, then the profession should take an interest in urging the erection of fire escapes to hotels and factories. The recent series of dreadful conflagrations in such buildings, offers emphatic examples of the pressing need for such avenues of exit.

It is hard fate enough to have to endure the cookery of the average hotel, without incurring the added danger of being cooked one's self.

The Cholera in Mexico.

The Government organ of the Mexican State of Chiapas publishes a long article on the choleraic disease which has ravaged that State, and has not yet disappeared. The General Government is asked for assistance, want and misery being prevalent where the epidemic raged. Sanitary cordons confined the disease to the hot region. It is said that "Whole families died in a single night. On some plantations there are only three or four

people left alive. Many bodies have been devoured by the dogs, because those who were stricken were at once abandoned. The town of Tuxtla had 8,000 inhabitants, 600 of whom are dead. Of the 6,000 in Tonalá, upwards of 1,000 are dead. The town of Chiapas suffered most severely, twenty to thirty persons dying daily."

Personals.

—It is said that the death of Mr. Critchett, the eminent English oculist, was hastened by remorse for a grave mistake made by him in an operation.

—Dr. H. Helmholtz has been raised to the rank of Baron, on account of his great services to physiology.

—Dr. F. Pierce, of Worcester, Mass., was recently arrested for treating erysipelas by local application of kerosene, thus causing "blisters and horrible suffering." They must have queer kerosene in Massachusetts; it don't blister down this way.

—A negro who is alleged to be 138 years old lives in Warren county, Miss. We have observed that such extraordinary age is attained only by Indians, peasants, or negroes, whose birth-date is unknown.

Items.

—A woman 102 years old, a native of Rhode Island, died recently in Providence.

—Medicine is radically a sacred profession and connected with the highest priesthoods, or rather itself the acme and outcome of all priesthoods and divinest conquests of intellect here below—*Carlyle*.

—In storms of controversy there is nothing to be found but the billow that moves to mischief and the foam that disappears.—*Page*.

—A large lunatic asylum has recently been erected at Bayreuth.

—The difference between a druggist and a farm laborer is that one is a pharmacist, while the other is a farm-assist.

—For the first three weeks of the present year the death rate of Providence, R. I., showed an increase over last year.

—A servant girl in Trenton, N. J., recently died from a dose of oil of tansy, taken probably to produce abortion. Post-mortem examination showed that she was not pregnant.

—Medical professor to raw student: "Where is the glottis?" "I don't know, sir. I think you put it on the shelf in the dissecting room with the rest of your surgical instruments."

—The *Official Messenger* publishes a decision of the Medical Council of St. Petersburg, condemning the homeopathic remedy for diphtheria, which has lately been tried there in the hospitals of the Red Cross Society, as false and dangerous.

—The Trustees of the Butler Hospital for the Insane, at Providence, intend to raise a beneficiary fund of \$150,000. One lady of Providence has offered \$50,000, and others have added \$25,000.

—For the year 1883 the Academy of Medicine, Paris, offers seventeen prizes, the total amount of money being over 60,000 francs. The largest prize is one of 25,000 francs (\$5,000), which will be given to any one who, in the judgment of the Academy, has found a remedy against diphtheria.

—Four clergymen, one Roman Catholic and the others Episcopal, have been arrested at Fort Smith, Ark., for violating a proclamation of the Mayor closing the churches and public schools and prohibiting public assemblages, on account of the prevalence of scarlet fever in the city. They were held in bail for trial.

—"What on earth makes you announce that you extract teeth without pain? Didn't I hear every patient you had up here yell?"

"You did, sir," replied the peripatetic dentist, "but those were shrieks of joy which they uttered, sir! They were so delighted, sir, at being painlessly relieved, that they could not restrain their enthusiasm!"

—The question of nationality has at last found its way into medicine. The French doctors in Nice are up in arms against their English and other foreign brethren established in that favored health resort. A general meeting of the former body has been held, at which protests were entered against the manner in which alien practitioners monopolize the most lucrative practice. Amongst other points which were urged, it was stated that many of the intruders are not qualified French physicians, and consequently have no right to practice anywhere in France.

Corrections.

Line 13, page 117, February 3, 1883, *defects* should have the place of *objects*.

The last paragraph in the article should have been made a foot-note to the sentence ending with the fifteenth line on page 119.

QUERIES AND REPLIES.

J. E. F., Jan. 13th last, will probably cure his patient of urticaria (hives), by prescribing 40-grain doses, four to six hours apart, of *sulphite of soda*. At all events, I have lately succeeded, in an intractable case, with this remedy.

MATHEY-CAYLUS' GLUTEN

SILVER

1854

CAPSULES

OF

PURE COPAIBA AND OTHER MEDICINES.

SILVER

1854

Adapted and recommended for the cure of recent or chronic Gleet, Fluor Albus, etc., etc.

The MATHEY-CAYLUS' CAPSULES, coated with gluten, present the most perfect mode for administering Copaiba, Cubebs, Norway Tar, Turpentine, and other remedies, the disagreeable odor and taste of which are often a hindrance to their use. This mode of preparing capsules, which has been approved by the Academy of Medicine, has been recommended in their clinical lectures by eminent Professors in the hospitals of Paris, as well as in those of New York and London.

By the first physicians of the hospitals of Paris, London, and New York.

SPECIAL ADVANTAGES OF MATHEY-CAYLUS' GLUTEN CAPSULES.—Being formed of thin, transparent, and readily assimilated coating, they so cover and disguise the medicine to be given, that it can be taken without disgust, but with ease. In this respect, they differ widely from the gelatine capsules, which have a hard, thick coating, which swells beyond measure, in the stomach, are hard to be swallowed, and what is of great importance, they create disturbance in the digestive functions.

The special advantage of the coating of gluten consists in the fact that, notwithstanding its extra thinness, and although it softens under the action of the gastric juice, it can pass the stomach without breaking, and only in the intestines is the medicinal matter liberated; this accounts for the fact that Mathey-Caylus' Capsules never cause the nausea, eructations, and dyspeptic symptoms, which are complained of by many persons using other preparations.

Finally, their regular ovoid form, which is so favorable to swallowing, their pleasant appearance, which dispels all disgust, and the advantage of being entirely free from taste and smell, recommend the use of these capsules even to the most delicate persons.

Thankful to the Medical Profession for the liberal patronage heretofore bestowed upon us, we hope that they will continue their favors, and we are convinced that they will never have any reason to regret the generous welcome they have given to our preparations.

MATHEY-CAYLUS' CAPSULES are never sold, except in bottles having the following inscription printed in the glass: MATHEY-CAYLUS A PARIS. And each bottle contains 64 capsules, making them the cheapest capsules in the market.

The following different kinds of Mathey-Caylus' Gluten Capsules are now offered:

COPAIBA AND TANNIC ACID,
COPAIBA AND S. N. OF BISMUTH,
COPAIBA AND CATECHU,
COPAIBA AND MAGNESIA,
COPAIBA, CUBEBS AND ALUM,
COPAIBA, CUBEBS AND RHATANY,
COPAIBA AND RHATANY,
COPAIBA AND CITRATE OF IRON,
COPAIBA AND CUBEBS,
COPAIBA PURE,
COPAIBA, CUBEBS AND CARB. OF IRON,

VENICE TURPENTINE, NORWAY TAR, PURIFIED,
CUBEBS AND TURPENTINE,
CUBEBS AND TANNATE OF IRON,
CUBEBS AND ALUM,
CUBEBS PURE,
COPAIBA AND MATICO,
COPAIBA, IRON AND OIL OF SANDAL,
COPAIBA AND OIL OF SANDAL,

CODMAN & SHURTLEFF'S ATOMIZING APPARATUS.

PRICES REDUCED.

THE COMPLETE STEAM ATOMIZER (Patented March 24, 1868.)

All its joints are hard-soldered.

Every one is tested by hydrostatic pressure, to more than one hundred pounds to the square inch. It cannot be injured by exhaustion of water, or any attainable pressure, and will last for many years. It does not throw spirits of hot water, is convenient, durable, portable, compact, and cheap, in the best sense of the word. Price \$5.00. Postage 59c.

Brass parts, nickel-plated, additional, \$2.00.

Neatly made, strong Black Walnut Box, with convenient Handle, additional, \$2.50. Postage 44c.

THE BOSTON ATOMIZER. (Patented.) SHURTLEFF'S ATOMIZING APPARATUS. (Patented.)

The most desirable Hand Apparatus. Rubber warranted of the very best quality. Valves imperishable, every one carefully fitted, and will work perfectly in all positions. Price \$3.50.

The Bells are adapted to all the Atomizing Tubes made by us.

Each of the above Apparatus is supplied with two carefully-made annealed glass Atomizing Tubes, and accompanied with directions for use. Each Apparatus is carefully packed for transportation, and warranted perfect.

TANRET'S PELLETIERINE.

For the **TREATMENT of TAPE-WORM (Tænia Solium).**

This new Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France, for the treatment of Tape-worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker, Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Prof. Laboulbène, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and if certain preliminaries are observed success will be insured.

PELLETIERINE is prepared by **Mr. CHAS. TANRET, Pharmacien de First Class, 64 Rue Basse du Rempart, Paris.**

Boudault's Pepsine.

IN POWDER, also WINE, ELIXIR, SYRUP, PILLS, AND LOZENGES OF PEPSINE.

Since the introduction of Pepsine by Boudault, in 1854, BOUDAULT'S PEPSINE HAS BEEN, AND IS STILL CONSIDERED, **THE MOST RELIABLE**, as is attested by the awards it has received at the Exhibitions of 1867, 1868, 1872, 1873, and in 1876 at the Centennial Exposition in Philadelphia.

IT IS THE ONLY PEPSINE USED IN THE PARIS HOSPITALS.

Careful tests will enable any one to satisfy himself that BOUDAULT'S PEPSINE HAS A DIGESTIVE POWER AT LEAST **DOUBLE** that of the best Pepsines in the market, and that it is really the cheapest.

It is Sold in 1 ounce, 8 ounce, and 16 ounce Bottles.

Beware of so-called French Pepsines bearing fictitious names, and prescribe Boudault's only.

BLANCARD'S PILLS

OF UNCHANGEABLE IODIDE OF IRON.

Blancard's Pills of Iodide of Iron are so scrupulously prepared, and so well made, that none other have acquired a so well deserved favor among physicians and pharmacists. Each pill, containing one grain of proto-iodide of iron, is covered with finely pulverized iron, and covered with balsam of tolu. Dose, two to six pills a day. The genuine have a **reactive silver seal** attached to the lower part of the cork, and a green label on the wrapper, bearing the fac-simile of the signature of

Blancard

Pharmacien, No. 40 Rue Bonaparte, Paris.

Without which none are genuine.

MALTINE.

MALTINE is a concentrated extract of malted Barley, Wheat, and Oats. In its preparation the temperature does not exceed 150° Fahr., thereby retaining all the nutritive and digestive agents unimpaired. Extracts of Malt are made from Barley alone, by the German process, which directs that the mash be heated to 212° Fahr., thereby coagulating the Albuminoids and almost wholly destroying the starch digestive principle, Diastase.

MEDICAL ENDORSEMENTS.

We append, *by permission*, a few names of the many prominent Members of the Medical Profession who are prescribing our Maltine Preparations.

J. K. BAUDUY, M. D., St. Louis, Mo., Physician to St. Vincent's Isane Asylum, and Prof. Nervous Diseases and Clinical Medicine, Missouri Medical College.

WM. PORTER, A. M., M. D., St. Louis, Mo.

E. S. DUNSTER, M. D., Ann Harbor, Mich., Prof. Obs. and Dis. Women and Children University, and in Dartmouth College.

THOMAS H. ANDREWS, M. D., Philadelphia, Pa., Demonstrator of Anatomy, Jefferson Medical College.

B. F. HAMMEL, M. D., Philadelphia, Pa., Supt. Hospital of the University of Pennsylvania.

F. R. PALMER, M. D., Louisville, Ky., Prof. of Physiology and Personal Diagnosis, University of Louisville.

HUNTER MCGUIRE, M. D., Richmond, Va., Prof. of Surgery, Med. Col. of Virginia.

F. A. MARDEN, M. D., Milwaukee, Wis., Supt. and Physician, Milwaukee County Hospital.

L. P. YANDELL, M. D., Louisville, Ky., Prof. of Clinical Medicine and Diseases of Children, University, Louisville.

JOHN A. LARRABEE, M. D., Louisville, Ky., Prof. of Materia Medica and Therapeutics, and Clinical Lecturer on Diseases of Children in the Hospital College of Medicine.

R. ODGEN DOREMUS, M. D., L.L.D., New York, Prof. of Chemistry and Toxicology, Bellevue Hospital Medical College; Prof. of Chemistry and Physics, College of the City of New York.

WALTER S. HAINES, M. D., Chicago, Ill., Professor of Chemistry and Toxicology, Rush Medical College, Chicago.

E. F. INGALLS, A. M., M. D., Chicago, Ill., Clinical Professor of Diseases of Chest and Throat, Woman's Medical College.

MALTINE is prescribed by the most eminent members of the Medical profession in the United States, Great Britain, India, China, and the English Colonies, and is largely used at the principal Hospitals in preference to any of the Extracts of Malt.

42—We will forward gratuitously a 1-lb. bottle of any of the above preparations to Physicians who will pay the express charges. Send for our 28-page Pamphlet on Maltine for further particulars. Address,

A. A. MEUNIER, M. D., Montreal, Canada, Prof. Victoria University.

H. F. BIGGAR, M. D., Prof. of Surgical and Medical Diseases of Women, Homœopathic Hospital College, Cleveland, Ohio.

DR. DOBELL, London, England, Consulting Physician to Royal Hospital for Diseases of the Chest.

DR. T. F. GRIMSDALE, Liverpool, England, Consulting Physician Ladies' Charity and Lying-in Hospital.

WM. ROBERTS, M. D., F.R.C.P., F.R.S., Manchester, England, Prof. of Clinical Medicine, Owens' College School of Medicine; Physician Manchester Royal Infirmary and Lunatic Hospital.

J. C. THOROWGOOD, M. D., F.R.C.P., London, England, Physician City of London Hospital for Chest Diseases; Physician West London Hospital.

W. C. PLAYFAIR, M. D., F.R.C.P., London, England, Prof. of Obstetric Medicine in King's College, and Physician for the Diseases of Women and Children to King's College Hospital.

W. H. WALSH, M. D., F.R.C.P., Brompton, England, Consulting Physician Consumption Hospital, Brompton, and to the University College Hospital.

A. WYNN WILLIAMS, M.D., M.R.C.S., London, England, Physician Samaritan Free Hospital for Diseases of Women and Children.

A. C. MACRAE, M. D., Calcutta, Ind., Dep. Insp.-Gen. Hosp. Ind. Service, late Pres. Surg., Calcutta.

EDWARD SHOPPEE, M. D., L.R.C.P., M.R.C.S., London, England.

LENNOX BROWN, F.R.C.S., London, England, Senior Surgeon Central Throat and Ear Hospital.

J. CARRICK MURRAY, M. D., Newcastle-on-Tyne, England, Physician to the N. C. H. for Diseases of Chest.

J. A. GRANT, M. D., F.R.C.S., Ottawa, Canada.

BEEF PEPTONIDS.

A CONCENTRATED POWDERED BEEF, PARTIALLY DIGESTED AND COMBINED WITH AN EQUAL PORTION OF GLUTEN.

We have pleasure in presenting, for the consideration of the Medical Profession, "BEEF PEPTONIDS." We consider this product the most valuable that ever emanated from our Laboratory, and we feel confident it will be welcomed by the Profession in all parts of the world.

BEEF PEPTONIDS contains *only* the *nutritious portions* of the beef. It contains *no water* and *no inert matter* of any kind. We combine the dry Extract of Beef with an equal *portion* of Gluten to prevent a tendency to deliquescence, and in order to present the preparation in a powdered and portable form. It is well known that Gluten is the most nutritious substance found in the Vegetable Kingdom, and in nutritive elements is closely allied to Beef.

Four ounces of BEEF PEPTONIDS represents as much nutritive and stimulating properties as forty-eight ounces of the best lean Beef.

Four ounces of BEEF PEPTONIDS contains more nutritive elements than ten pounds of any extract made by Liebig's formula, and from four to six times more Albuminoids and Fibrinoids than any Beef Extract ever offered to the Medical Profession.

Our machinery and process for the production of BEEF PEPTONIDS are perfectly adapted to the *elimination* of all inert portions of Beef, and the *retention* of all the nutritive constituents.

BEEF PEPTONIDS *is much less expensive than any other preparation in the market, as it contains neither water nor inert matter.*

The favor our preparation of BEEF PEPTONIDS received at the hands of DRs. AGNEW, HAMILTON, BLISS, REYBURN, WOODWARD, BARNES, etc., the corps of eminent physicians, who employed the preparation with so much advantage in the treatment of the late PRESIDENT GARFIELD, proves conclusively its great value, not only as a food to be taken by the mouth, but also, how important an agent it has been found in feeding by the rectum.

Please refer to the very able article of DR. D. W. BLISS, in *New York Medical Record*, July 15, 1882, in which he so frequently refers to BEEF PEPTONIDS having been used to so great an advantage, not only in the case of the late PRESIDENT GARFIELD, but many others as well.

We employ a reliable and experienced person to select the Beeves before they are slaughtered, and to superintend the killing and dressing. Great care is exercised in this respect, and none except the most healthy and suitable Beeves are employed in making our BEEF PEPTONIDS.

Every physician will appreciate the importance of this care, for an Extract made from diseased Beef would not only be deleterious, but would, in many cases, produce lasting injury and fatal results.

The use of BEEF PEPTONIDS is indicated as follows:

Convalescence from all diseases, Fevers, Pneumonia, Weak Digestion, Diarrhoea, Dysentery, Phtisis, Cholera Infantum, Marasmus, Sea Sickness, Excessive use of Alcoholic Stimulants, Per Rectum in all cases where the stomach cannot digest the food, and in debility resulting from any cause. Also, a valuable adjunct in voyages and camp life.

We will be pleased to have the Profession everywhere test our assertions regarding this preparation, and for that purpose we will be happy to mail a sample to any regular practitioner desiring it; also circulars fully explanatory.

Thanking the Profession for generous support in the past, we beg to remain,

Very respectfully,

REED & CARNRICK,

1351-1402 182 FULTON ST., NEW YORK.

TO PHYSICIANS.

IODIA.

FORMULA.—Iodia is a combination of Active Principles obtained from the Green Roots of *STILLINGIA*, *HELONIAS*, *SAXIFRAGA*, *Menispermum*, and Aromatics. Each fluid drachm also contains five grains IOD.-POTAS. and three grains PHOS.-IRON.

DOSE.—One or two fluid drachms (more or less, as indicated) three times a day, before meals.

IODIA is the *Ideal* Alterative. It has been LARGELY PRESCRIBED in Syphilitic, Scrofulous, Cutaneous, and Female Diseases, and has an Established Reputation as being the best Alterative ever introduced to the Profession.

Ex-President Illinois State Medical Society.

BROMIDIA.

FORMULA.—Every fluid drachm contains fifteen grains EACH of pure Brom.-Potas. and purified Chloral, and one-eighth grain EACH of *gen. imp ext.* Cannabis-Ind. and Hyoscyam.

DOSE.—One-half to one fluid drachm in WATER or SYRUP, every hour until sleep is produced.

BROMIDIA is the *Hypnotic par excellence*. It produces refreshing sleep, and is exceedingly valuable in Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, etc., and will relieve when opiates fail. Unlike preparations of opium, it does not lock up the secretions. In the Restlessness and Delirium of Fevers it is absolutely invaluable.

1282-tf

ELECTRICITY!!!

DR. JEROME KIDDER'S

ELECTRO-MEDICAL APPARATUSES

ARE THE BEST,

Owing to the Simplicity of Operation, Durable Construction, and the Physiological Qualities of Electricity they produce.

AWARDED by the "AMERICAN INSTITUTE" THE HIGHEST PREMIUM FOR THE YEARS 1872 TO 1882, inclusive, and in 1875 the GOLD MEDAL, as an award of the first order of importance. Also, the HIGHEST AWARD at "CENTENNIAL EXHIBITION" and at "CINCINNATI INDUSTRIAL EXHIBITION" (two Silver medals), in fall of 1881 and 1882, Silver Medal (Highest Award), Charleston, S. C., Exposition fall of 1882, and wherever and whenever exhibited in competition.

Our machines are highly recommended by eminent Scientific Practitioners, and give perfect satisfaction. The No. 5 Tip Battery Apparatus (see cut) is the only perfect and complete portable apparatus. It does not require constant attention, and is operated by a form of battery that will remain active for months without replenishing the solution: and the annoyance and inconvenience due to crystallization in the cell is entirely obviated in the form of

battery operating our Faradaic Machines. The solution is composed of one part common sulphuric acid to eleven parts of water, with a small quantity of mercury; thus the cost of replenishing the solution is but a trifle.

We manufacture a complete line of Office Faradaic Batteries, also Cabinet Batteries, Galvanic, Galvano-Cautery and Combined Galvanic and Faradaic Apparatus, either with tip cells or upright cells. Galvanic Batteries from 4 to 36 cells constantly on hand, and an improved Pocket Induction Apparatus. Our machines are constructed under Letters Patent for marked and decided improvements, rendering them superior to all others, either here or abroad. All other parties claiming highest awards for above mentioned are fraudulent, being made to deceive the public. To distinguish the genuine from the spurious, send for illustrated catalogue. Address, 1350-1401

JEROME KIDDER MANUFACTURING CO.,

820 Broadway, New York.

TAMAR INDIEN-GRILLON.

A laxative, refreshing, and medicated Fruit Lozenge, agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION, CEREBRAL CONGESTION, HEADACHE, INDIGESTION, BILE, HEMORRHOIDS, etc., etc., by augmenting the peristaltic movement of the intestines, without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness, and the same dose always produces the same effect, that is to say, never needs increasing. These properties render "Tamar" invaluable to the weak and debilitated, and especially to ladies previous and subsequent to their accouchement. It is recommended by the most eminent Physicians of Paris; notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

Prepared by E. GRILLON, Pharmacien de 1ère classe, 27 Rue Rambuteau, Paris. To be had of all respectable Druggists throughout the world. 1349-1400

Madame La Chapelle's "Health Preserver."

A REVERSE CORSET for preventing and overcoming Uterine disease. Preëminently useful during Pregnancy. Especially adapted to treatment of Functional Derangement. It affords **immediate satisfaction.** Heat and Pain throughout the region of the back and pelvis. "fullness and dragging down," prolapsed bowels, ovarian weakness, troubles of the Bladder, and attendant reflex troubles of Heart, Brain, Stomach, and Liver, are relieved by its **application.** Every one made to order, from glove kid and calf, and are very elegant. In measuring give **exact** size (under all clothing) of Waist; Abdomen at Umbilicus; Hips, largest part; Thigh; and length from Waist to Pubes. *Measurement must be accurate to insure perfect fit.*

Retail Price, \$15; to Physicians, \$10. Send for Circulars and Measuring Cards.

SELECT MEDICAL OPINIONS.

Sir HENRY MARSH, Bart., M.D., T.C.D.,

Physician in Ordinary to the Queen in Ireland.

"I have frequently prescribed Dr. De Jongh's Light Brown Cod-liver Oil. I consider it to be a very pure Oil, not likely to create disgust, and a therapeutic agent of great value."

Dr. JONATHAN PEREIRA, F.R.S.,

Author of "The Elements of Materia Medica and Therapeutics."

"It was fitting that the author of the best analysis and investigations into the properties of Cod-liver Oil should himself be the purveyor of this important medicine. I know that no one can be better, and few so well, acquainted with the physical and chemical properties of this medicine as yourself, whom I regard as the highest authority on the subject. The Oil is of the very finest quality, whether considered with reference to its color, flavor, or chemical properties, and I am satisfied that for medicinal purposes no finer Oil can be procured."

Sir G. DUNCAN GIBB, Bart., M.D., LL.D.,

Physician and Lecturer on Forensic Medicine, Westminster Hospital.

"The experience of many years has abundantly proved the truth of every word said in favor of Dr. De Jongh's Cod-liver Oil by many of our first Physicians and Chemists, thus stamping him as a high authority and an able Chemist, whose investigations have remained unquestioned."

Dr. PROSSER JAMES,

Lecturer on Materia Medica and Therapeutics at the London Hospital.

"I have always recognized your treatise on Cod-liver Oil as the best on the subject, and adopted its conclusions as to the superiority of the Light Brown over the Pale Oil. I have the less hesitation in expressing myself in this sense, since I am only endorsing the opinion sent to you more than twenty years ago by Dr. Pereira, my illustrious predecessor in the chair of Materia Medica at the London Hospital."

DR. DE JONGH'S LIGHT BROWN COD-LIVER OIL

Is sold ONLY in Capsuled Imperial Half-Pints, \$1.00, by most Druggists throughout the United States.

SOLE CONSIGNEES, ANSAR, HARFORD & CO., 77 STRAND, LONDON.

AGENTS IN THE UNITED STATES,

DR. WHEELER'S

ELIXIR FERRI ET CALCIS PHOSPH. CO.

LACTO-PHOSPHATES prepared from the formula of DR. DUSART, of Paris.

Compound Elixir of Phosphates and Calisaya—A Chemical Food and Nutritive Tonic.

This elegant preparation combines with a sound Sherry Wine percolated through Wild Cherry Bark and Aromatics, in the form of an agreeable cordial, 2 grs. Lacto-Phosphate of Lime, 1 gr. Lacto-phosphate of Iron, 1 gr. of Alkaloids of Calisaya Bark, Quinia, Quindia, Cinchonia, and fifteen drops of free Phosphoric Acid, to each half ounce.

In the various forms of Dyspepsia, resulting in impoverished blood and depraved nutrition, in convalescing from the Zymotic Fevers, Typhus, Typhoid, Diphtheria, Smallpox, Scarlatina, Measles, in nervous prostration from mental and physical exertion, dissipation and vicious habits, in chlorotic, anemic women, in the stremuous diathesis in adults and children, in malarial diseases, after a course of quinia, to restore nutrition, in spermatorrhoea, impotence and loss of sexual orgasm, it is a combination of great efficacy and reliability, and being very acceptable to the most fastidious, it may be taken for an indefinite period without becoming repugnant to the patient. When Strychnine is indicated the Liquor. Strychnie of the U. S. Dispensatory may be added, each fluid drachm of the solution to a pound bottle making the 64th of a grain to a half fluid ounce of the Elixir, a combination of a wide range of usefulness.

The chemical working of the formula is peculiar to the originator, and the various imitations and substitutes offered by druggists will not fill its place.

Dose.—For an adult, one tablespoonful three times a day, after eating; from seven to twelve years of age one dessert-spoonful; from two to seven, one teaspoonful.

Prepared by T. B. WHEELER, M.D., MONTREAL, D.C.

Please mention THE MEDICAL AND SURGICAL REPORTER.

A. M. LAWSON,

689 BROADWAY, N. Y.

JENSEN'S CRYSTAL PEPSIN,

IN ARTIFICIAL CRYSTALS,

Strictly Inodorous and Tasteless, and Perfectly Soluble in Water without Acid.

THIS PEPSIN, now so popular with the profession, has given an impetus to the consumption of this drug. Physicians of the highest standing, who before the introduction of this active Pepsin, with good reason, entirely abandoned the use of Pepsin, are now the most eager in prescribing JENSEN'S CRYSTAL PEPSIN, whenever it is indicated. Since the knowledge of its great solvent power (gr. j. of it will dissolve the boiled whites of two or three eggs) has been established, it has come to be utilized in many novel ways by the medical profession, for instance, as a substitute for morphia, chloral, etc., as hypnotics, relieving gastric troubles where the above remedies have been productive of the morphia and chloral habits. In removing diphtheritic patches it is successfully used combined with water, glycerine, and muriatic acid, and the same composition, diluted with more water, as a spray in bronchial troubles, dissolving muco-purulent matter, as well as in various forms of catarrhal affections.

THIS PEPSIN

Has also been used with success in dissolving and evacuating coagulated blood in the bladder, dispensing with surgical operations in such cases. Many other novel applications could be mentioned, were it not for want of space. It is found to be FORTY times stronger than saccharated pepsin. One to three grains is an active dose.

KEPT BY ALL DRUGGISTS.

JENSEN'S

BEEF PEPTONE,

IN TRANSPARENT GLASSY SCALES.

One ounce represents one pound of beef, less fat and a small portion of earthy matter, which precipitates after the process of digestion is entirely completed, thus presenting a true and highly azotized nutrient in the most concentrated form possible. This is the first Beef Peptone ever offered to the profession in a strictly completed and unmixed state, and will stand the most severely scientific test as to perfectness. For rectal as well as oral administration it offers to medicine a *new agent* by which to overcome asthenic inanition, and thus combat one of the worst features of acute as well as chronic diseases.

JENSEN'S

BEEF PEPTONE WITH ROCK CANDY.

Also in Transparent Glassy Scales, but a Trifle Larger.

Devised to overcome the long-felt difficulty in feeding sick children who object to food in any hitherto known form, but never refuse candy. They will to the gratification of all interested feed themselves with this sweet Peptone, and ask for more. One ounce of this Peptone represents one-half pound of beef.

Both of these Peptones are put up in bottles holding one ounce, eight ounces, and one pound, retailed at 65 cents per ounce.

The above preparations are only manufactured and put up exclusively as specialties by

DR. CARL L. JENSEN,

865 North 26th Street, Philadelphia, Pa.

Grimault & Co's Pharmaceutical Products.

Prepared with scrupulous care, under the immediate supervision of a practical chemist, at their model laboratory at Neuilly, near Paris.

Offices and Salesrooms, No. 8 Rue Vivienne, Paris.

The attention of the Medical Profession is directed to a few leading products:

Dusart's Syrup and Wine of Lacto-Phosphate of Lime,

The properties of which are scientifically founded on physiological experiments, and have received the sanction of several years' successful trial by the French and English medical profession, as producing durable reconstituent effects in all cases of *Cachexia* or *Adynamia*, when nutrition has been impaired by acute or chronic complaints.

As an article of diet it acts as a general excitant of all the nutritive functions, ensures digestion, brings back or increases the appetite, enriches the milk of the mother, and generally improves the vital energies. As a medicament it is chiefly used in convalescence, teething, rickets, and imperfect growth, dyspepsia, various nervous diseases, wounds, fractures, and all complaints of the osseous system.

Dusart's Syrup of Lacto-Phosphate of Lime and Iron is a ferruginous medicament, specially invaluable for the above cases, when complicated with anemia.

Dusart's work on the "Physiological and Therapeutic Action of Phosphate of Lime" will be sent free to any physician, on application to Messrs. E. FOUGERA & Co.

GRIMAULT & CO'S MATICO CAPSULES.

These Capsules are coated with Gluten, and contain the essential Oil of Matico, combined with the Balsam of Copaiba solidified by Calcined Magnesia. Besides its very special activity, the Essence of Matico has the property of disinfecting the Balsam of Copaiba, and of making it endured by the stomach, and does not cause any unpleasant eructations.

LEBAIGUE'S DIALYSED IRON, or pure Peroxide of Iron,

IN SOLUTION, WITHOUT THE AID OF ACIDS OR OTHER SOLVENTS.

It is nearly tasteless; does not blacken the teeth; is very readily absorbed; will not constipate, or cause any disturbance of the digestive apparatus, and is tolerated by persons who could not support any other preparation of Iron. It is offered in the form of a *Solution*, which is generally preferred; or of an *Elixir*, when a slight stimulant is desired.

The above and all the other preparations of Messrs GRIMAULT & CO., and information in regard to the same, may be obtained at all times from

Messrs. E. FOUGERA & CO., Importing Pharmacists, New York.

1342-67

PACKER'S TAR SOAP.

ABSOLUTELY PURE AND NON-IRRITATING.

MADE FROM VEGETABLE OILS, PINE TAR, AND GLYCERINE.

A perfect soap should be made from pure and sweet oils, and clean, well-washed alkalis. Such is **Packer's Tar Soap**. It is combined with distilled **pine-tar**, and hence has had the most gratifying effects in the treatment of Dermatological Diseases, as chafing, eczema, erythema, seborrhea, herpes, etc.

As a Disinfectant, Antiseptic, and Detergent, it is admirably adapted for use in ulcers, foul wounds, fetid discharges, bed sores, and similar conditions. For the bath, toilet, and shampoo, it is unrivaled. 25 cents per cake, from Druggists.

It is supplied to Hospitals, Asylums, and Physicians, in one pound bars, at reasonable prices.

P. O. Box 2985. 1349-1406ow THE PACKER MFG. CO., 100 Fulton St., New York.

PROCTER'S PEPSIN (SACCHARATED).

This standard article is prepared from *Pepsin*, carefully purified and freed from mucus, and is not a *dried Peptone*. It is inodorous and non-deliquescent, and retains its digestive power indefinitely. It is so well known that extended comment is superfluous. We would, however, call attention to its uniform purity and solubility, which, with extraordinary *digestive power*, commend its use in preference to other less carefully made articles. It is tested to the solution of 250 grains of coagulated albumen by 10 grains of Pepsin.

PROCTER'S "PEPSIN FORTIOR" (Stronger or Concentrated Pepsin). A powerful form of Pepsin, eligible when minimum dose is desirable. It is of the same exceptional purity with our *Procter's Pepsin*, while the strength is far greater. Dose, one to three grains. 1308-1360,ly

Manufactured by WM. PROCTER, JR., CO., S. W. Cor. 9th and Lombard Sts., Philadelphia.

Three Years' Graded Course.

THE AUXILIARY LITERARY TERM commences on the third Monday in April, and continues until June 30th.

THE AUTUMN PRELIMINARY TERM begins on the first Monday in September, and continues four weeks.

THE WINTER SESSION commences on the first Monday in October, and continues six months.

The Faculty of the Medico-Chirurgical College desire to call the attention of Medical Students generally to the unsurpassed advantages for both Didactic and Clinical Instruction afforded by the curriculum of the College. Daily Review Examinations are held by the members of the Faculty, upon the subjects of the didactic lectures—no outside quizzes are allowed. Practical Clinical Instruction is a marked feature of the Course. Every Student is required, by the rules of the College, to examine and study cases at the different clinics, and give attendance to Practical Chemistry and Pharmacy, in the Laboratories of the College; also, the study of Practical Anatomy, Operative Surgery and Bandaging, Physical Diagnosis, Practical Gynecology and Analysis of the Urine, is obligatory on each member of the class. In addition to the regular daily clinics of the College, Special Clinical Lectures will be delivered during the Winter Session, by a corps of Clinical Professors, on different diseases, such as those of the Eye and Ear, Throat, Nervous System, Skin, Diseases of the Mouth, etc. They will be the same as those usually given in the Spring term of other Medical Colleges. All these courses are without extra charge, except that of Practical Anatomy. In addition, there is an Auxiliary Literary Term, for the especial benefit of those Students who may desire the advantages of a thorough English and Classical Education. The Medico-Chirurgical College is the first Medical College to take this important step. For further particulars and announcements, address the Secretary of the College,

LONG ISLAND COLLEGE HOSPITAL, BROOKLYN, N. Y.

The Reading and Recitation Term will Commence September 27th, 1882, and Close at the beginning of the Regular Term.

*The Regular Term will Open January 24th, 1883, and continue five months.

In the Reading and Recitation Term the Recitations are supplemented by Laboratory Work, Lectures, and Clinics.

In the Regular Term the Laboratory Work, Lectures, and Clinics are supplemented by oral and written examinations; and the senior students are admitted, in sections of ten or more, to the wards of the Hospital, where they are thoroughly trained in practical medicine.

The Laboratories, Recitation and Lecture Rooms, Amphitheatre, Wards of the Hospital, and Dispensary Rooms, are all in the same building, thus affording convenient and ample opportunities for a thorough education in practical medicine and surgery.

There are over 12,000 patients treated annually in the Hospital, which is under the control of the College authorities, and therefore available for practical teaching.

For circulars, address

Prof. S. G. Armor, M. D., Dean.

Registered

Trade Mark.

Put up in 1, 5, 10, 25, 50, and 100-lb. cans. Samples furnished on application. The post-office laws forbid anything of an oleaginous nature being sent through the mail.

In chemical composition, Cosmoline (Unguentum Petrolei) is an oleaginous hydrocarbon, corresponding to the heavy petroleum oils, and containing a large amount of the paraffines and olefines of the formulæ $C_{16}H_{34}$ and $C_{16}H_{32}$. It contains but a small percentage of the paraffines and olefines corresponding to the formulæ C_7H_{16} and C_7H_{14} , respectively, and the offensive and irritating properties of the crude oil have been carefully removed. In the process of purification, no acids, alkalies, or other chemicals are employed, and no injurious additions of any kind are made to the natural product. The result is a semi-solid, translucent substance, with a faint odor and unctuous feel.

Cosmoline (Unguentum Petrolei) melts at about 100° Fah. (38° Cent.); and boils at about 625° Fah. (329° Cent.); its specific gravity is about 0.875 at 60° Fah.

As it contains no oxydizable or organic matter capable of change by putrefaction or fermentation, and is absolutely without affinity for moisture, it offers to the profession an admirable unguent, which can never decompose, ferment, or become rancid in any climate or temperature.

PHILADELPHIA, July 10, 1880.

MESSRS. E. F. HOUGHTON & Co.: I have for a number of years made extensive use of Cosmoline (Unguentum Petrolei), and consider it a most valuable article for surgical purposes. Either as a dressing by itself, or as a vehicle for the application of medicaments, it is greatly superior to lard or other fatty matters, especially by reason of its non-liability to change by time or temperature.

Yours truly,

JOHN H. PACKARD, M. D.

1031 WALNUT STREET, PHILADELPHIA.

MESSRS. E. F. HOUGHTON & Co.: I have used extensively Cosmoline (Unguentum Petrolei) both in Dispensary and private practice, with very great satisfaction. As a vehicle in making ointments it is invaluable, and far superior to lard, for the reason that it will not become rancid or undergo chemical change like the latter, when exposed to the atmosphere. I cannot too highly commend it as an application in various skin diseases.

Yours truly,

JOHN V. SHOEMAKER, A. M., M. D.,

Physician to the Pennsylvania Free Dispensary for Skin Disease.

208 WEST 34TH STREET, NEW YORK.

MESSRS. E. F. HOUGHTON & Co.—Gents: I fully appreciate the value of your Cosmoline, or Unguentum Petrolei, and prescribe it frequently in ointments. Fluid Cosmoline I have used constantly for several years, as a lubricant of urethral sounds. It is the cleanest oil I know of for this purpose.

Yours truly,

GEO. HENRY FOX.

DOSE.—Two teaspoonfuls alone, or mixed with twice the quantity of soft water, to be taken thrice daily, with meals.

The principles upon which this discovery is based have been described in a treatise on "THE DIGESTION AND ASSIMILATION OF FATS IN THE HUMAN BODY," by H. C. BARTLETT, PH.D., F.C.S., and the experiments which were made, together with cases illustrating the effect of Hydrated Oil in practice, are concisely stated in a treatise on "CONSUMPTION AND WASTING DISEASES," by G. OVEREND DREWRY, M.D.

In these treatises the Chemistry and Physiology of the Digestion of the Fats and Oils is made clear, not only by the description of a large number of experiments scientifically conducted, but by cases in which the deductions are most fully borne out by the results.

 Copies of these valuable works will be sent free, on application, to all who mention THE MEDICAL AND SURGICAL REPORTER

HYDRATED OIL, HYDROLEINE, WATER AND OIL,

May be described as partially digested oil, which will nourish and produce increase in weight in those cases where oils or fats not so treated are difficult or impossible to digest. In CONSUMPTION and other WASTING DISEASES the most prominent symptom is EMACIATION, of which the first is the starvation of the fatty tissues of the body, including the brain and nerves. This tendency to emaciation and loss of weight is arrested by the regular use of HYDROLEINE, which may be discontinued when the usual average weight has been permanently regained.

The ordinary so-called emulsions of Cod-liver oil and other fats, WHETHER PANCREATIZED OR NOT, merely remain in the form of a coarse mechanical mixture for a short time after agitation. The digestion of oil having in no sense been artificially produced, still devolves upon those functional powers the deficiency of which is the most prominent symptom in these cases.

HYDROLEINE is not a patent medicine or a secret preparation; the formula is on every bottle. Can be taken by the most delicate stomach; is immediately assimilated.

The permanence and perfection of the emulsion, and the extreme solubility of the HYDRATED OIL, solely prepared and sold by us under the name of HYDROLEINE, is shown by its retaining its cream-like condition as long as the purest Cod-liver Oil will retain its sweetness. Unlike the preparations mentioned, or simple Cod-liver Oil, it produces no unpleasant eructation or sense of nausea, and should be taken in such very much smaller doses, according to the directions, as will insure its complete assimilation; this, at the same time, renders its use economical in the highest degree.

To brain-workers of all classes Hydrated Oil is invaluable, supplying as it does the true brain food.
Economical in use—certain in result Tonic—Digestive and Highly Nutritive.

EXPECTORANTS.

Manufacturing Chemists,

DETROIT, MICH.

Respectfully solicit the attention of practitioners of medicine to their preparations of the following drugs, premising their statement of the claims made for them by mention of the fact that such claims are, in each instance, the legitimate deductions from reports in their possession (and copies of which will be gladly furnished gratis on application) of results following the use of the drugs in the practice of competent and conscientious physicians :

Philadelphia,
206 and 208 Market St.

QUEBRACHO.

Aspidosperma Quebracho.

Although of comparatively recent introduction, Quebracho came to us so endorsed by the results of physiological and clinical experience as to place it at once in a place among the more reliable drugs. These experiments have been copious and convincing, fixing quebracho as an agent possessing a peculiar property in relieving dyspnoea due to whatever cause, the cyanotic hue of lips and surface disappearing under its use, and the distress of the patient being distinctly ameliorated.

Quebracho supplies, in its marked properties, a pressing want, especially in the treatment of pneumonia or other affections of the lungs attended by dyspnea. In such self-limited affections the desideratum is to sustain the patient until the disease shall have run its course, and many have succumbed because of the want of an agent which should do what quebracho is claimed to do. That it is a remedy of indispensable value in acute pulmonary inflammations is attested by abundance of testimony in our possession, and which will be supplied gratuitously, collated from both private and hospital practice.

DOSE—FLUID EXTRACT OF QUEBRACHO (P., D. & CO.),
20 MINIMS TO A FLUIDRACHM.

LIPPIA MEXICANA.

An agreeable anodyne and demulcent expectorant, introduced by us to the profession of this country on the authority of Dr. A. H. Saxton, of Baltimore, Md. Dr. Saxton received a sample of the plant for trial from a gentleman (a chemist by profession), who, while traveling in Mexico, in 1877, had observed its characteristic properties from its use among the natives. The botanical position of the plant was fixed by Dr. Vasey, of the Agricultural Department at Washington. The reports following its use by others fully corroborate that originally made by Dr. Saxton, and have established *Lippia Mexicana* as a remedy of great value in the relief of distressing cough, whether due to acute inflammation or to more chronic pulmonary lesions, as in phthisis, chronic bronchitis, etc.

DOSE—FLUID EXTRACT LIPPIA MEXICANA (P., D. & CO.),
30 MINIMS TO A FLUIDRACHM.

YERBA SANTA.
(*Eriodcyon Californicum.*)

Although this indigenous plant has been before a profession for several years, it is to be feared that it is not as fully appreciated as its inherent merits demand. The cause of this is the fact that it has not been recorded the thorough trial to which an agent possessing the properties claimed for it, is entitled. It is a potent stimulant of superior quality, and while exercising a favorable influence over mucous membranes wherever situated, has a peculiar influence over that of the respiratory passages. The testimony in support of this statement is too voluminous for introduction at this place, but will be cheerfully furnished on application to us. We prepare a fluid and a solid extract.

DOSE—FLUID EXTRACT YERBA SANTA (P., D. & CO.), 3 ss to 3 j.
SOLID EXTRACT YERBA SANTA (P., D. & CO.), gr. iii to gr. x.

This plantigracious to Chilli, was introduced to the English profession by Dr. William Mitchell, the famous English theoretician and collaborator of Ringer, as a remedy for the "Winter Cough" of elderly people. Dr. Mitchell's favorable reports have been endorsed by the experience of many practitioners of this country for its efficacy in chronic bronchial affections of a non-inflammatory character. It is a prominent place on the list of remedies for chronic bronchial affections of a non-inflammatory character, and the German Hospital of Valparaiso, speaks in high terms of its influence being alleviative and demulcent. It is a valuable adjuvant in cough medicines.

We solicit for this new drug a thorough trial in the catarrhal affections peculiar to this season, confident as we are that it will prove a valuable expectorant.

CHEKEN.
(Myrtus Chekan.)

DOSE—FLUID EXTRACT CHICKEN (P., D. & CO.), 1 TO 2 FLUIDRACIMS

THE STANDARD PREPARATION OF IRON.

SOLUTION. FERROUS MALATE.

(4 Grains to fluid drachm.)

A chalybeate that has all the virtues and none of the defects of all the present officinal preparations of iron.

We have the pleasure and satisfaction of placing in the hands of the profession a preparation of iron for which all the above claims have been verified, both in the laboratory and by the clinical experience of many of the leading physicians of the country.

Solution Ferrous Malate is a proto-compound, the form in which iron is most readily assimilated, and being united with a fruit acid in solution, it is rendered palatable, and does not injure or blacken the enamel of the teeth. It does not consipite, nauseate, produce headache, or any of the other unpleasant effects resulting from the use of the ordinary forms of iron.

The Solution Ferrous Malate forms elegant and clear solutions with dilute Phosphoric Acid, Fowler's Solution, and the vegetable tonics. It is also compatible with, and does not form inky mixtures with, compounds containing tannin, such as the Clachona preparations, Port Wine, French Brandy, etc. This property cannot be claimed for any ferruginous remedy of the Pharmacopœia.

Sulphocyanide of potash does not strike a deep red color with a ferrous salt, as is the case when it is added to a solution of a ferric salt. Free tannin, however, added to Solution Ferrous Malate will turn it black instantly, as it does all preparations containing iron.

Sold on physicians' prescriptions only. Supplied by Druggists. Send for circulars and sample.

MANUFACTURED ONLY BY

THE AMERICAN PHARMACEUTICAL MANUFACTURING CO.,

Office, N. E. Cor. Tenth and Arch Sts.,

PHILADELPHIA.

We are also agents for the famous Harris' Faradic and Galvanic Batteries. The finest instruments in the world. They range in price from \$15 to \$30, according to the number of currents. 137-138

LECTURE.

SPLenic LEUCÆMIA.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF
THE UNIVERSITY OF PENNSYLVANIA, BY

WILLIAM PEPPER, M. D., LL. D.,

Professor of Clinical Medicine in the University of Pennsylvania.

Reported by WM. H. MORRISON, M. D.

GENTLEMEN:—You will remember that at the last lecture, we were considering a case of splenic leucæmia. I pointed out to you the general symptoms by which we recognize this group of cases; that without apparent cause, the patient is noticed to become weak; his ordinary work tires him more than usual. With this, he becomes paler. The weakness and anæmia gradually increase until he is compelled to quit work. There is nearly always breathlessness on effort and palpitation of the heart under excitement or exertion. Often a little puffiness about the ankles is observed, sometimes a little puffy look about the eyes, and later, there may be considerable œdema. Auscultation shows an anæmic murmur over the base of the heart. Hemorrhages from various surfaces, particularly from the nose, and sometimes from the bowel, are not rare. If the eye ground is examined, small, scattered, retinal hemorrhages, perhaps interfering with vision, may be found. In some of these cases, examination of the blood shows no increase in the number of the white corpuscles, while in other cases, there is a great increase in their number. The normal relation is about one white to two hundred and fifty red. This may come to be one white to fifty red;

one to five; one to three; or as in the case you saw last week, the white and red may be equal in number.

Dr. Wm. E. Hughes has carefully counted the corpuscles in that patient, and I have here his report. In a cubic millimetre of healthy blood there are about 5,000,000 red globules and about 20,000 white globules. In this case there were but 1,300,000 red (a reduction of 75 per cent.), while there were 1,245,000 white globules. This is a most remarkable degree of leucæmia. The red corpuscles in such cases do not form good rouleaux; they are not of as bright a red as they should be, and frequently their shape is altered. The white globules are also much changed, and you will often find, as is stated to be the case here, that "it is a matter of difficulty to decide in some instances whether a corpuscle is red or white." Not only is there a great change in the appearance of the corpuscles, but there is also evidence of marked alteration in their development and constitution. They are diseased.

I further stated to you that while the weakness and anæmia were gradually increasing, it is noticed in some cases that there is enlargement of the spleen, with perhaps a little or no affection of the glands. This constitutes splenic leucæmia. In these splenic cases the liver is often enlarged. In other cases, without much involvement of the spleen, the lymphatic glands become enlarged. This is usually first observed in the glands of the neck, then of the axilla, then of the groin, and finally of the abdomen. This is lymphatic leucæmia. In these cases the spleen may be moderately or even considerably enlarged. Lastly, there is a group of these cases where you find neither en-

largement of the spleen nor affection of the glands; where, during life you can put your hand upon no lesion, but where, after death, there is found hyperplasia of the lymphatic elements of the marrow of the bones. We thus have a medullary form of the disease. In one class of these cases the number of white globules is not increased, while in another it is greatly increased. The former class is termed pseudo-leucæmia, and the latter leucæmia. We thus have pseudo-leucæmia and leucæmia of three varieties, splenic, lymphatic, and medullary.

Another symptom which I might mention is albuminuria. Albumen is not rarely present in moderate amount, and is usually dependent upon the alteration in the blood and the excessive filtration of blood serum through the malpighian tufts. Occasionally there is irritation of the renal cortex, causing the appearance of a few tube-casts.

In approaching a case of this kind, your first duty is to determine whether the anæmia has resulted from some functional cause, so to speak, or some palpable, demonstrable, removable cause. You will first examine to see if the patient has been subjected to loss of blood. This is a frequent cause of anæmia. The hemorrhage need not be a large one. A little leakage of blood, as from bleeding piles, will gradually bring about a condition of intense anæmia. Another cause of extreme anæmia is the long continued discharge of pus, as from a fistula in ano or an old bone abscess. Any interference with primary assimilation is an exceedingly frequent cause of anæmia. The various forms of dyspepsia must rank among the most common and the most frequently overlooked causes of anæmia. A trifling chronic diarrhœa, perhaps characterized by only one loose stool every day, or every alternate day, will suffice in persons whose blood-making powers are weak, to bring about extreme anæmia.

Last week I alluded to the influence of nervous shock or strain as a factor (I do not say that it was the essential cause) which I have met with in cases of anæmotosis; but nervous shock or strain is frequently met with as the essential cause of functional anæmia. Organic disease of the kidney, with a constant drain of albumen, may bring about intense anæmia. Diabetes mellitus causes the same condition.

Failing to find any of these conditions, you should search for organic disease of the various organs. Incipient phthisis, ulcer of the stomach, cancer of the stomach, and cirrhosis of the liver in its early stage, may all give rise to intense anæmia.

Failing to find any of these diseases, you look for affections of the spleen and lymphatic glands, and in the absence of these, you would suspect lesions of the marrow of the bones.

There is one cause of anæmia which I have purposely omitted, as its consideration will be required in the study of the case now before you. I refer to chronic malarial disease. I mention this particularly, since it gradually brings about intense anæmia, which is not rarely associated with enlargement of the spleen. As the splenic variety of leucæmia is the most common, you will sometimes find it difficult to decide whether the patient is suffering from the effects of chronic malaria or from anæmotosis.

This gentleman, aged 33 years, has come to us from Williamsport. He has consulted a number of physicians (fourteen, I believe), but has not been able to obtain any positive opinion in regard to the nature of his disease. I have not had an opportunity of examining him, but will try to elicit the history from his wife. He was employed on the railroad for a number of years, but lately has been serving in a clerical position. He is described as being of singularly good habits, and I cannot find any error of life to throw light upon his condition. He has used tobacco to excess. He has been failing for the past two years. There has been a progressive loss of flesh from 148 pounds to 110 pounds. He then began to lose color and strength; but during this time he had a "terrible appetite." He would eat a number of times during the day, and his wife would have to get up at night and cook for him. He did not crave unnatural things. He was always a great drinker of water. During the past year the thirst and hunger have, to some extent, disappeared.

About nine months ago a hard, movable, painless mass, not very large, was noticed low down in the abdomen, about the median line. This has grown steadily. He got out of breath when walking any distance, and sometimes complained of palpitation of the heart and dizziness in stooping. About a year ago, there was a little swelling around the ankles and half-way up to the knee, which lasted two weeks. It has not again appeared.

Twice during the progress of his disease there have been profuse hemorrhages; once after the lancing of a carbuncle, when he nearly bled to death; and once after the extraction of a tooth, when the doctor and his wife worked all night trying to stop the bleeding. He has also had several hemorrhages from the nose, brought on by

pulling out the hairs or scratching the mucous membrane.

Lastly, we come to a very unusual symptom. About a year ago he began to grow hard of hearing. The ears were examined and some hardened wax removed, after which he heard better. Six weeks ago he went to bed hearing as well as usual, but when he awoke, he was stone deaf. He could not hear the loudest shouting. There has been a slight return of hearing on the left side, and on yelling into the ear he seems to hear a little. This sudden deafness is, under any circumstances, very rare.

In regard to malarial disease, he has never had chills and fever, and did not live in a malarial district.

I do not find any enlargement of the glands of the neck, of the axilla, or of the groin; but the mass, described by his wife, is very perceptible as causing an irregular enlargement of the abdomen. It runs obliquely from above downward, and from left to right, and is most prominent in the left hypochondrium. The right side of the abdomen is soft and yielding, but on the left there is an indurated smooth mass. Percussion shows that the liver dullness extends from the fifth interspace to two and a half inches below the margin of the ribs in the line of the nipple. Below the liver on the right side there is resonance, until I get to the right flank, where it is flat as far up as the line of the anterior-superior process of the ilium. Thence backwards, it is flat. I turn the patient on the right side to see if this is liquid, but the dullness is the same. The whole of the left side is flat on percussion. This dullness extends from the left hypochondrium, downwards to a little above the left groin. Examining this mass more carefully, I note that it is universally resisting, of a smooth surface, and painless. It is slightly movable. I cannot determine its thickness. I draw the outline thus, and you see that it corresponds with that of a spleen much enlarged.

While I have been making this examination, Dr. Hughes has made a rapid enumeration of the blood globules. I have here his report. There are 2,275,000 red corpuscles to the cubic millimetre (a reduction of about one-half), and 1,085,000 white corpuscles in the same space. The white corpuscles are large and well formed.

We must then regard this as a case of splenic leucæmia, entirely uncomplicated by any enlargement of the lymphatic glands.

Let us see whether there is any explanation for this mass other than enlarged spleen. Malarial spleen it is not. The youth of the patient, the

absence of pain, the absence of tenderness and the absence of secondary growths in the lymphatic glands, exclude the idea of cancerous disease. The sallow cachectic look is very much like the so-called cancerous cachexia, but this complexion is so often met with in connection with other diseases, that you cannot give to it any definite diagnostic value. This mass is not a tumor of the liver. That organ is enlarged, but in its place. It is not a tumor of the pancreas or spleen.

The organs which would explain a mass of this kind are the kidneys, possibly the omentum and lymphatic glands, and the spleen. We see very large kidneys in hydronephrosis and in rare cases of cancer; but under these circumstances, the mass forms deeply, and it is only when it has reached an advanced stage, that it is felt prominently near the surface of the abdomen; but this tumor was quite noticeable nine months ago. This tumor is without pain, and carcinoma would be excluded for the reason previously given. We should recognize hydronephrosis by fluctuation. This mass is entirely without fluctuation.

The omentum is in rare cases the seat of morbid growths. I have seen enormous tumors, difficult of diagnosis, filling the abdomen and depending upon neoplasms in the omentum and mesenteric glands. In such cases the tumor is more symmetrical and has a transverse instead of an oblique shape, as here. Again, we should expect such a mass to be more nodular and irregular, and the seat of more pain and tenderness.

The direction of this mass, the dullness directly in contact with the walls of the abdomen, and continuous with the dullness of the spleen, the ovoid shape of the tumor, associated with the presence of leucæmia, make me feel confident that this mass is an enlarged spleen.

The sudden deafness was, I think, due to a hemorrhage into the middle ears. I shall have the ears carefully examined, to see if any evidences of hemorrhage can be found. If there has been no hemorrhage into the middle ear, it must have occurred inside of the cranium and press upon the auditory nerves; but this, is I think, improbable. (See note at end of lecture.)

The prognosis in these cases is always unfavorable. The history is that with apparently causeless ups and downs, their course is on the whole downward. It is not usual for a great loss of flesh to occur. In the case of splenic leucæmia which you saw last Saturday, the weight was the same as when he was in the best state of health, although the white and red blood globules were equal in number. The maintenance of the body

weight is not necessarily a favorable feature in the prognosis. We should base our prognosis on improvement in the crasis of the blood, on the disposition of the red globules to assume their natural proportion and appearance, and the white to decrease in number, and with this arrest of growth, and decrease in size of the glands or spleen. I have seen cases where such arrest occurred for a long time, and where for a time there was apparently a diminution in size. I have seen cases where undoubtedly certain glands became smaller while others grew larger. The favorable features are a slight degree of leucæmia, the preservation of nearly the normal number of red globules, the maintenance of the digestion and appetite, absence of hemorrhage and dropsy, the maintenance of the tone of the heart, and the arrest or recession of the splenic or lymphatic enlargements.

The treatment is unsatisfactory. I need not say that if in a bad case of anæmia you come across a definite cause, and you remove that cause and give the patient a carefully regulated diet, rest, good hygiene, iron, nutrients and tonics, the anæmia disappears and the patient gets well.

Again, if in examining such a case you find organic disease of some of the great viscera, as incipient phthisis, stenosis of the aortic orifice of the heart, gastric ulcer, or cancer, or disease of the kidney, the prognosis of the anæmia is dependent upon the prognosis of the organic disease, and the treatment of the anæmia is the treatment of the organic disease. If you can benefit the one, you can benefit the other.

Lastly, if in a case of persistent anæmia you find evidences that it is one of this peculiar group of cases associated with organic changes in the blood-making glands, the indications for treatment are of course controlled by the question whether or not anything can be done to check the organic disease in these tissues. The remedies which you would naturally think of under such circumstances would be the alteratives and absorbents. Thus mercury has been persistently used in these cases. I have employed it in large and in small doses. I have, however, given up its use in large doses, but still employ it in minute doses continued for a long time. Let me tell you why I prescribed mercury in the case before you last week. That gentleman's sister developed enlargement of the lymphatic glands, which continued under various methods of treatment. At last, small doses of mercury were given and persisted in for a long time. Under this plan of treatment, the health was entirely restored and the enlarge-

ments disappeared. He had prescribed for himself full doses of mercury, and had continued them until he had deranged his digestion, but it is his positive assertion (and knowing his skill as a physician, I attach great weight to his statement) that the lymphatic glands have grown smaller, and the spleen has grown softer and smaller. We must not, however, attach too much importance to these apparently good effects, for I have seen the same results under various plans of treatment. A consideration of these two facts has, however, led me to continue mercury in his case. I have given him the mild chloride of mercury in one-twelfth of a grain doses, four times a day. I have requested him to report weekly the condition of his appetite, digestion, weight, and color, so that I may judge of the effect of the treatment upon the nutrition and the crasis of the blood.

Iodide of potassium has been tried, but has proved of no value. Arsenic was long ago recommended, and has recently been again brought forward, but the universal experience is that it is of no permanent utility. Alkalies in large amounts have been employed, and I am disposed to try the resolvent effect of large doses of ammonium chloride continued for a long time. How it is that this drug promotes the removal of large masses, such as fibroid tumors, is a question that has excited much discussion and amazement. I have seen fibroid tumors which had been growing steadily, entirely disappear under the use of large doses of chloride of ammonium continued for from three to ten years. I have had patients take this drug regularly three times a day for ten years. In the present case, I propose to employ this drug in large doses for a long time.

Iron has of course been given in large and small doses, with the hope of restoring the crasis of the blood, but it has failed to do so. Cod-liver oil, phosphates, preparations of malt, and all the class of nutrients, have been employed without avail.

The attempt has been made to cure the disease by extirpating the hypertrophied tissue. Glands have been cut out, but the remaining glands have grown all the more rapidly. In cases of splenic leucæmia, the spleen has been removed, and this solves the question promptly, for all such cases have died. The condition of the blood, the feeble state of the nutrition, and the debility and dyscrasia of the system are such as to render excision of the spleen (hazardous and almost surely fatal as it is under any circumstances) quite inadmissible in splenic leucæmia. I should most strongly

discountenance removal of the spleen in this disease.

Another operation has been recommended, that is, the interstitial injection through the abdominal walls of ergotin, or some other substance which will produce contraction and absorption by local action. In these cases of splenic leucæmia, adhesions are often found uniting the peritoneum and spleen, and the long-continued irritation seems to render the peritoneum less sensitive than usual; so that I should not hesitate very long before performing this operation, if benefit was to be derived from it. I have tried this plan, but it excited so much local disturbance that I could not persist with it.

The important elements of treatment are a rigid attention to the diet, extreme care in correcting indigestion, particularly diarrhœa, the maintenance of a tranquil, resigned spirit, the use of the lightest and most gentle exercise, abundant rest, particularly in view of the feeble condition of the heart, and the internal use, in long-continued courses, of full doses of chloride of ammonium or of minute doses of mild chloride of mercury.

These cases are rare; yet the experience of the past few weeks, when on successive days we have had before us a case of lymphatic pseudo-leucæmia, a case of splenic and lymphatic leucæmia and a case of uncomplicated splenic leucæmia, will show you that they may at any moment present themselves, and that you should be able to recognize them.

—The following is the report of the examination of the ear made by Dr. George Strawbridge:

Six weeks ago suffered from a sudden loss of hearing, binaural, with more or less giddiness lasting up to the present time.

This giddiness is more pronounced if the eyes are closed and in the standing position, also has difficulty in walking with closed eyes. Has had a previous deafness, three months before the present attack, affecting the left ear only. This was relieved by the removal of a plug of cerumen. Right ear at that time remained normal.

Present condition: Right ear hearing, cannot hear even very loud sounds. External canal and tympanic membrane normal.

Left ear hearing, can hear very loudly spoken words. External canal and tympanic membrane normal.

Tuning fork on the incisor teeth heard by the left ear.

Pharynx and nasal passages normal.

Diagnosis: An effusion of blood or serum into the semicircular canal and cochlea, with conse-

quent labyrinthine pressure; this acting on the auditory nerve elements distributed to the contents of the semicircular canals would explain the vertigo, and pressure on the cochlear branch would cause the high degree of deafness.

Examination of the optic nerve gave negative results.

This patient died November 8, 1882. The post-mortem examination was made 18 hours after death, by Dr. William Willits. His report states that the examination was limited to the abdomen. The liver weighed 10 pounds; to the eye, its structure appeared normal. The gall bladder was normal. The spleen weighed 5 pounds; structure but slightly changed. The kidneys were slightly enlarged.

COMMUNICATIONS.

THE HEALTHFULNESS OF THE SEASHORE RESORTS—SOME PERTINENT FACTS ABOUT MALARIA.

BY, BOARDMAN REED, M. D.,

Of Atlantic City, N. J.,

President of the Atlantic County Medical Society, and of the Atlantic City Board of Health.

Is there malaria at any of the resorts along the New Jersey coast? Prof. Alfred L. Loomis, of New York, says: "Salt-water marshes are, as a rule, especially free from malaria; but mix salt and fresh waters, as in some of the New Jersey marshes, and you have the conditions for generating the poison. Marshes that rest on a substratum of sand are not so malarial as those that rest on limestone, clay, or mud."

This may be accepted as authoritative. Physicians in sending away patients will do well to bear it in mind. Wherever rivers empty into the sea, there such a mixture occurs. Another fact which should also be remembered is that, *ceteris paribus*, the more rank the growth of vegetation in any place, whether at the shore or in the country, the greater the likelihood of miasmatic fevers arising toward the end of summer. Decaying vegetable matter, in the presence of heat and moisture, probably always engenders a certain amount of malaria, though when the material thus decaying is small, the poison produced may be only infinitesimal.

Owing to the luxuriance of their crops of vegetation, the newer settlements on the Western prairies have always been cursed with malarial fevers; but just in proportion as the soil is culti-

vated and wild nature is brought into subjection, such diseases disappear, except where perpetuated by sluggish streams.

Our New Jersey beaches, except those near the mouths of fresh-water streams, enjoy, as a rule, almost entire immunity from the paludal poison, since the dry sand, which constitutes their soil, is impregnated with salt, and the vapors of chlorine, iodine, etc., borne over them from the ocean, and across the salt-water bays and marshes at the rear, are decidedly anti-septic and anti-malarial. The older and more highly-improved places, where all rank vegetation is kept down, should be especially exempt, as experience proves them to be.

The numerous virgin beaches which have recently been made the sites of imposing paper cities, may have attractions for robust tourists and for some quasi invalids, who enjoy hunting and fishing, and prefer being away from the fashionable crowd; but a more certain exemption from malaria is not by any means to be included among their advantages, notwithstanding the oft-reiterated assertions of the land agents and of other gentlemen who are the hopeful possessors of corner lots at such places. The projectors of these embryonic sanitarium are always firmly convinced that it is very unhealthy at Atlantic City, Cape May, Long Branch, and the other older resorts.

Since many persons, including physicians, confide in such interested statements without requiring proofs or making any discrimination between the places attacked, a few plain facts bearing upon the healthfulness of some of these resorts may be of interest. At Cape May an epidemic of fever is said to have broken out in one of the large hotels last summer, and was attributed to an attempt to sewer into a sluggish creek in the vicinity. Whatever the cause, it will no doubt be remedied before another season opens. This experience seems to confirm the opinion of many good sanitarians, that the system of storage in properly constructed vaults, with dry removal at frequent intervals, may be safer for the level seaside beaches than any system of sewerage which does not include flush tanks, forcing pumps, or other expensive apparatus, and an outlet far away from the town, which is sometimes impracticable. Though there has never been such an epidemic in any Atlantic City hotel, the newspapers in commenting upon this occurrence assumed in some instances that both places were equally involved. The following facts are a sufficient answer to all such insinuations.

Atlantic City, as is well known, is wholly sur-

rounded by unmixed salt water, besides having six miles of salt meadows behind it, and rests upon a bed of dry sand—therein fulfilling the two conditions laid down by Prof. Loomis as essential to immunity from malaria. No considerable fresh water stream empties within many miles of it. My personal experience of the place, dating back thirteen years, during five years of which I have been residing in it all the year round, affords strong evidence against the probability of malaria originating here. Myself and family have always enjoyed exceptionally good health here, and in particular have never suffered from fevers, nor from malaria in any form.

In my practice among invalid visitors, I see a great deal of malaria. It is one of the diseases for which people come here, particularly in winter, and when they remain long enough, they do not often come in vain.

Those coming from the more decidedly malarious localities, such as Washington, D. C., some portions of New York city, and from most places along the New Jersey shore of the Delaware river, are liable to have some manifestation of malarial character developed shortly after their arrival, especially if they should be suddenly chilled or suffer from hepatic disturbance, as often happens in consequence of over-indulgence of the enormous appetite usually provoked by the sea air. This phenomenon is well understood by those accustomed to treat patients from miasmatic regions, and is particularly referred to by Prof. Bartholow. It is an occasional though transient result of the first contact with sea-air anywhere, and I have seen the same thing at the mountain resorts, as a result of the abrupt change, in persons whose systems were saturated with malaria in a dormant form.

Visitors from non-malarious places are never affected in such a way; and the permanent residents of Atlantic City are practically exempt from malarial diseases. The exceptions in my experience have been so exceedingly few as to prove the rule. For instance, I have never seen a single undoubted case of intermittent fever in one of this class, except in persons who had lately returned from visits to notoriously malarial localities; though in a fatal case of diabetes mellitus attended by me, there was at the last some fever of an obscurely intermittent type.

Following is one of several striking cases I might report of persons who, after long residing in Atlantic City without having any malarial symptoms whatever, visited miasmatic regions and suffered from severe attacks of intermittent on their return:

A young lady who, with her family, had been under my professional care since the first year of my residence here, and always enjoyed a perfect immunity from malarial affections, spent a few weeks with friends at St. Catherine's, Canada, during the month of September. Her friends warned her not to go out of doors after nightfall for fear of malaria, but the advice was not strictly followed. After returning home—within one or two weeks—she had a severe attack of genuine ague. This was in 1881, and though her system seemed to be thoroughly charged with the poison in an unusually active form, it yielded in due time to treatment, and it was so completely eliminated that last fall she, though remaining here till the end of September, had no return of the disease whatever, and has remained free from it up to this time—February, 1883.

*As for remittent fever, I have never seen a case of it among the residents, and but a single one among visitors. This one case was in the person of a young lady from New York city, some of whose family had suffered with the same form of fever at home shortly before. She recovered entirely before leaving here.

It may be asked, are there never fevers of any kind at Atlantic City? Not in winter or spring, if we except the exanthemata; but it would be singular indeed if none of the two or three hundred thousand people who visit the place every summer were ever imprudent enough in their eating, drinking, and bathing, to develop febrile affections. Sporadic cases of a mild continued fever, with sometimes enteric complications, are seen occasionally during the latter part of the season. These are usually among a class of persons not at all attentive to the rules of hygiene, who bathe in the surf from one to two hours daily (not always excepting the catamenial period in the case of ladies), and then immediately afterward gorge themselves at dinner, following this within a few hours with a supper, frequently of raw oysters even in midsummer, when the bivalves are "in the milk," and very putrescible. After such a day, half the night is often spent in revels of one sort or another, with or without a plentiful accompaniment of stimulants. There are not merely hundreds, but thousands, who go through with such a programme almost daily in the summer for several weeks, or until cholera morbus, fever, or some other acute disease, results as a natural consequence. Those who are a little less reckless may have the inevitable penalty deferred till they reach home, and then, as they usually forget to tell the doctor the whole story, both he

and the friends are likely to lay the blame upon the air at the seashore. The bad water furnished at some of the inferior houses is no doubt sometimes a factor in the causation of fevers and diarrhoeas, and one for which there is now not the slightest excuse in Atlantic City, since an abundance of the purest water is to be had. But of this, more further on.

The only wonder is that any of the thousands who thus disregard all hygienic considerations, in the matter of bathing especially, should ever escape serious illness. Yet last summer I saw but two visitors with any form of protracted fever. One was a youth recently from a college in an inland town, where his friends believed that he imbibed the germs of the disease. But he had been spending an hour and a half every day in the surf for two or three weeks, and this alone would have ensured the development of any tendency to fever by the long-continued and repeated congestions of all the internal organs thus produced. It was a very light attack of continued fever, with a slight diarrhoea at one stage, but no rose-colored spots nor tympanites, and he was well again in three weeks. The other patient, a married lady, had been ailing ever since a recent visit to Florida, where she had relatives, and she had been excessively addicted to surf bathing. She had enteric fever, and recovered in four weeks. Both these patients stopped at boarding-houses of the less pretentious class, at one of which the drinking water was of more than doubtful quality; yet there was but the one case of fever in either house, though both houses were full of people all summer. This fact renders it highly probable that the germs or tendencies which were the predisposing causes of these two cases were brought by the patients with them when they came here, and that they were developed by the exciting causes already alluded to.

At the numerous large and carefully conducted hotels where I regularly attended, there were no cases of fever of any kind at any time during the season, nor have there been any since. The same may be said of these hotels during the previous year. In the summer of 1881 I saw the following two cases only:

A young lady of by no means robust constitution was sojourning at a small boarding-house on the avenue farthest back from the ocean. She bathed every day from an hour to an hour and a half. After being here a few weeks, she developed a mild continued fever, with some diarrhoea for a few days, but with no other enteric symptoms. The temperature fell to the normal in two

weeks, but there was a slight return of fever subsequently, which protracted the convalescence one or two weeks longer. There were no other cases in the house, though, considering its cheap character, there might well have been without any fault thereby attaching to the hundreds of well-kept houses in more desirable parts of the town.

The other case was that of a gentleman, who with his wife and large family of children occupied a cottage on a prominent avenue. He went back and forwards to the city every week day, so that only his nights and Sundays were spent in Atlantic City. He had a moderately severe attack of typho-malarial fever and recovered in about four weeks, while his family who were here day and night all summer were none of them attacked: the inference is plain.

But as already intimated, considering the reckless habits of many visitors, and the large proportion of them who, coming directly from great cities where they breathed continually an atmosphere polluted by sewer gas and foul-smelling gutters, might be presumed to bear with them the germs of typhoid fever and other zymotic diseases, the only wonder should be that so exceedingly few develop any serious illness. It must be taken as a confirmation of the opinion that the typhoid poison, at least, if not the germs of the miasmatic fevers as well, more often gains access to the economy through the stomach than the lungs. There is much talk now-a-days about *malaria*—bad air—but more cases of disease, whether in city, country, or at the shore, probably arise from bad water.

The water supply of Atlantic City was, until recently, either from wells or cisterns. The former, used for drinking by the poorer classes of the residents only, furnish surface water of varying degrees of badness, yet many seem to drink it with impunity. The cisterns are generally well kept at all the better-class hotels, and then afford very pure water; but careless house-holders sometimes let them get dirty, when, of course, the water may become impure.

Henceforth, there need be no need of tolerating poor water at any house here, for the reason that an enterprising company has introduced an abundance of the purest running water in pipes from the mainland. This has been carefully tested both chemically and by being continuously in use in many houses since last August, and has been found pure and wholesome.

Our Board of Health, besides devoting ever-increasing attention to the duty of seeing that all garbage is removed daily from every house, and

that the drainage arrangements are maintained in the best possible condition, has just decided upon the appointment of a health inspector, an important part of whose duties it will be to analyze, periodically, the drinking water at every hotel and boarding-house. Indeed, I feel justified in saying, on behalf of the Board, that now that a water supply of unquestioned purity has been obtained, it is determined to spare no efforts necessary to preserve the famous air of the place pure and uncontaminated; and whatever further reforms shall be found essential to effect this, will assuredly be consummated.

HOSPITAL REPORTS.

STRUMA.

CLINIC OF PROF. E. ALBERT, IN VIENNA.

Translated* for the MEDICAL AND SURGICAL REPORTER,
by HUGO ENGEL, M. D.

Patient, a boy, æt. 14, has a rather large swelling in the region of the right anterior triangle of the neck. The tumor can easily be defined; backwards, it reaches as far as the sterno-cleido-mastoid muscle, but does not spread over it; that the abnormal enlargement does not include *different* tissues, is proven by the fact mentioned, and by its moving synchronously with the trachea at every act of deglutition. The tumor is, therefore, not a *malignant* one, as the skin over it can easily be put into folds, and is perfectly unchanged. The seat of the swelling is a physiological organ, the *glandula thyreoidæ*, and the swelling itself a struma, known by the proper name of *goitre*. If we examine its consistence, we feel a uniform, more or less coarse-grained mass, and we make the diagnosis of *struma parenchymatosa*.

If we now look at this nineteen-year-old girl, we observe on her also on the right side in the region of the thyreoidæ a swelling, with all the symptoms and signs of the first case, but here the mass of the tissue is a different one; we feel irregular, coarse nodules, and in one, especially large, we are able to detect fluctuation, so that we may suppose the existence of a cyst. The diagnosis here is therefore: *struma cystica*.

While the boy does not complain of any subjective symptoms whatever, the girl suffers, when ascending the stairs or a hill, from difficulty of breathing, dyspnoea, and of late, deglutition even has become rather painful to her.

With reference to these two cases, I wish to say a few words concerning the different varieties of struma, their importance and treatment. Notwithstanding the malady is not limited to certain localities, one may say, that in deep valleys of high mountains it is in reality *endemic*. Regarding their *morbid anatomy*, the strumæ, according to the changes the physiological tissue of the thyroid

*Bericht der Allg. Wiener Med. Ztg. aus der chirurg. Clinic des Prof. E. Albert, vom 19 August, 1882.

gland has undergone, are divided into several groups: most frequent and easiest to treat is the *struma parenchymatosa*, in which, according to Virchow, the single follicles hypertrophy and are forced apart by exuberant growth of interstitial tissue, to which facts is due the augmentation in size of the organ, and the uniform mass we feel. I can suppose, as is well known, that in their normal condition the single follicles of the thyreoidea are filled with a colloid mass.

If this substance becomes augmented in a *struma parenchymatosa*, then the latter presents some larger and smaller nodules, some of which, occasionally one or the other, are filled by soft, slimy contents, the colloid, and this morbid condition is meant, when we speak of *struma gelatinosa*. In case the gelatine-like contents of one such follicle should become perfectly soft, fluid, then we have cystic formation. Sometimes, however, it happens that the septum which separates two nodules from each other, totally dwindles away, is absorbed in consequence of pressure, so that a communication is the result, and at the same time one larger cyst is formed, a process which rarely takes place without hemorrhage, in consequence of which the fluid contents of a cyst assume a brown tint, resembling the color of the tincture of iodine. The sac in such a *struma cystica* presents a varying appearance. Sometimes its inner surface is smooth, often it contains membranous ridges, occasionally lime formations are noted, and even bony deposits are not so exceedingly rare.

Besides these three varieties, which are met with very frequently, there is occasionally seen a fourth form, the so-called *struma vasculosa*, in which not only the numerous veins of the thyroid gland, but also the different vessels, the arteries, are dilated to such a high degree that a really enormous *blood-tumor* results, which can easily be recognized and differentiated from the other varieties by its compressibility, flabbiness, and softness.

Notwithstanding it usually is a harmless disease, goitre may occasionally cause even death. The anatomical position of the thyroid gland explains to us, that a considerable enlargement of the latter, especially when extending deeply backward, will induce a partial compression of the œsophagus, and therefore difficulty in deglutition. But the trachea is also compressed, though in the beginning not in any threatening manner. The continuous pressure, however, causes the cartilaginous rings of the windpipe to undergo a metamorphosis; they become soft, and while a normal bronchial tube, placed upon a solid basis, stands erect, a trachea influenced by pressure from a *struma* will bend, and sometimes the angle formed will be rather pointed. Gradually the form of the trachea is totally changed, and it will happen, that a patient having previously experienced no difficulty whatever from his tumor, is suddenly, while making an incautious movement with his head, turning the same abruptly to the right or left, attacked, in consequence of the bending together of the trachea, by *suffocation*—and *death* may result.

Concerning therapeutics, there is a *medical* and a *surgical* treatment; the former, however, has its indication only in the parenchymatous variety,

and consists here in the application of iodine in some form or other, internally as well as externally. Internally either iodide of sodium or potassium, the tincture of iodine, or Lugol's solution, are administered in the usual doses. Externally it is best to employ the following solution: iodine, iodide of potassium and glycerine in the proportion of 1 : 5 : 100; this is brushed in a thin coat over the swelling, and it is preferable to make this application in the morning, as many patients, when the brushing is done at night, by inhaling the vapor of iodine, suffer from the disagreeable iodine-catarrh. Comparatively easy is the *surgical* treatment of the cystic degeneration of the thyroid gland. Totally to be disregarded is the simple *puncture*, which some surgeons practice to be certain as regards diagnosis. We say, to disregard, because, first, manual examination suffices to establish the diagnosis in an undoubtedly cystic goitre, and secondly, in case the cyst cannot easily be felt, colloid nodules may perhaps be punctured, and such accident is frequently followed by inflammation, nay even mortification. Of great importance, however, is the puncture, if it is followed immediately by the injection of iodine. The procedure here is the same as in cases of hydrocele, adhesive inflammation of the opposite membranes of the cystic sac being the desideratum. The first consequence of this operation is a greatly increased sensitiveness of the cyst; then plentiful exudation into the cavity follows. Within a few days the hyperæsthesia disappears, and then the swelling begins to dwindle away, and a few weeks later the process is finished—a small nodule being all that is left. Occasionally surgeons have endeavored to cause by double puncture and incision the formation of pus, and Billroth has reported several such cases. In large colloid goitres or in a *struma* with calcareous walls the gland has to be extirpated, if a radical cure shall be established. On account of the gland being physiologically rich, but pathologically still richer in blood, the operation is a difficult one. There are many cases on record, in which it has been necessary to apply as many as one hundred ligatures! The operation has often, if the trachea has suffered already decidedly, to be preceded by *tracheotomy*, as it has happened, that the death by suffocation, of which we made mention before, suddenly took place while the operation progressed.

When performing the operation for extirpation of the cyst, we have to remember that the carotid is pressed by the *struma* outward, and its position is sometimes so superficial that one can note its subcutaneous course, while the *jularis interna* is pushed towards the median line. Very difficult is the case if in an *accessory* thyroid gland a *struma* develops itself. Corny operated on such a *struma accessoria*, the seat of which was behind the œsophagus, *retro œsophagealis*, therefore. Exceedingly difficult to diagnosticate, and the consequences of which cannot be calculated, is a *struma* of a lobe, which has a pedicle, and reaches into the anterior mediastinum, a so-called *struma substernalis*.

Regarding the treatment of our two cases, in that of the boy we will apply iodine locally, while in the girl we shall puncture the cyst and follow this by injection with iodine.

MEDICAL SOCIETIES.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

The stated monthly meeting of the College was held in the Hall on Wednesday evening, February 7, 1883.

The new President, Dr. Alfred Stillé, presided and made a few introductory remarks.

Dr. S. Weir Mitchell presented five thousand dollars to the College, to constitute a fund for the purpose of giving, annually, a *conversazione*, reception, banquet, or some similar entertainment, which in the judgment of the council shall seem best calculated to promote the interests and welfare of the College and the profession.

A resolution of thanks and appreciation was tendered to the donor, and it was decided that the fund should be designated as "The S. Weir Mitchell Entertainment Fund."

Arsenical Paralysis.

Dr. Charles K. Mills read a paper on arsenical paralysis. Last fall several cases of poisoning from eating pie in which was subsequently found arsenic occurred in Norristown. Some of the victims, after suffering for varied periods from symptoms of gastro-enteritis, fully recovered; one died, and two were afflicted as the patient under Dr. M.'s care.

The patient, at first, was treated for *erratic malaria* by a homœopath, and after four days came under the care of Dr. Corson, of Norristown, who, recognizing the true nature of the trouble, endeavored to eliminate the arsenic by purgatives, and used iodide of potassium for its alterative effects—all without avail, as the patient grew rapidly worse, developing paralyzes, for which he came to this city and entered the Orthopædic Hospital, under the care of Drs. Mitchell and Mills.

His symptoms (all of the nature of paralysis) indicated myelitis; he was treated with hot and cold applications to the spine, combined with massage, and is now rapidly improving.

In answer to a question by Dr. Bartholow as to why efforts were not made by Dr. M. to eliminate the arsenic, it was replied that, as the patient did not come under his observation until four weeks after the ingestion of the poison, it was concluded that there was none to eliminate, since the best authorities all agree that if one poisoned by arsenic lives a week, the drug will have entirely disappeared.

In answer to a question by Dr. Gross, Dr. M. replied that while there was some abatement of sexual function, it was not lost.

Heloderma Horrida.

Drs. Mitchell and Reichert exhibited a living specimen of this lizard, and Dr. M. read a paper on the nature of the poison. The *Heloderma Horrida*, which is found in Arizona, is the only one of the lizard family that is poisonous. It is usually sluggish in its habits, and will not bite unless provoked; but when the full-sized lizard (it grows to a length of three feet) does bite, it produces a very poisonous wound, and can prove fatal. For the purpose of experiment, Dr. M. caused the lizard to bite on the edge of a saucer (which was no easy task, and required much pa-

tience, so unaccommodating was his lizardship) and when saliva commenced to flow, it was caught on a watch glass. Differing from the saliva of venomous reptiles, which is always acid, the spittle of the *Heloderma* is alkaline. A very small quantity injected into a pigeon, produced its effect in a tottering gait in less than three minutes, and caused death in less than nine. The specimen presented was fourteen inches long, fat and plump, and presented somewhat the coloring of a rattlesnake. Dr. M. expects an assortment of these lizards in the spring, when he will have more to say about them.

NEW YORK STATE MEDICAL SOCIETY.

The seventy-seventh annual meeting was held at Albany on Tuesday, Wednesday, and Thursday, February, 6th, 7th, and 8th, 1883; the President, Dr. Harvey Jewett, of Canandaigua, in the chair.

TUESDAY.

The session opened with an address by the President, in which he reviewed the great progress of our science of late years. He made reference to the act of 1872, creating a State Board of Examination, whose duty it should be to certify to the qualification of candidates for the honor of graduation from our medical colleges. The law was not made obligatory, and was not received with favor by the medical schools at the time, hence it has been inoperative and useless. He considers that it should be made compulsory.

He became eloquent in defense of the National Board of Health, and condemnatory of the niggardly action of Congress in the matter of appropriations thereto; and closed his address with a reference to Prof. James R. Wood, of New York city, Dr. George Burr, of Binghamton, and Dr. I. Foster Jenkins, of Yonkers, all prominent members of the Society, who have died since the last meeting.

Committee on Experimental Medicine.

The Secretary, Prof. John G. Curtis, of New York, read the report.

For the third time the Legislature of New York has expressed its disapproval of Mr. Bergh's antivivisection bill.

A communication from the Westchester County Society was received, transmitting the following resolutions, which had been adopted, in reference to the new Code:

Resolved, That this Society reaffirms its adherence to the principles of the Code of Ethics of the American Medical Association, and declares that, in its opinion, for a physician to extend professional recognition to irregular practitioners is to patronize and encourage irregular practice; and it is alike inconsistent with honesty of purpose and the pursuit of medicine as a science.

Resolved, That the Medical Society of Westchester County disapprove of the action of the New York State Society.

Resolved, That this resolution be referred to the State Medical Society at its next annual meeting.

Dr. D. B. St. John Roosa offered a resolution that this communication be referred to the Committee on By-Laws, and that the County Society be censured for its action in repudiating the By-

Laws of the State Society. He said he considered the tone of the communication as entirely improper, coming, as it did, from a district society to this Association, and criticising its proceedings.

Dr. Govan, of Stony Point, reminded the speaker that it would be highly inconsistent to condemn a county society for secession, since this Society itself has seceded from the American Medical Association.

Dr. Roosa denied most emphatically that the New York State Medical Society had seceded from any body. The American Medical Association is an unincorporated body, this Society being under no obligation to it, and never having subscribed to its rules. We do not consider ourselves in any way bound to obey the rules of the American Medical Association. This Rip Van Winkle body, this excursion association, was not thought of when the New York State Medical Society, incorporated in 1806, was already a scientific and important representative body of physicians.

Dr. Thos. F. Rochester, of Buffalo, said that the speaker was in error; this Society had bound itself to obey the rules of the American Medical Association, and had adopted its Code, and agreed to be bound by its provisions. If Dr. Roosa would turn to the proceedings of the Association, he believed that he would find that such a resolution had been passed by the New York State Medical Society.

Dr. Roosa—And abrogated last year.

Amid a call of several members for the question, a substitute for the resolution, offered by Dr. Piffard, that the communication be received and placed on file, was carried.

Monroe county presented a communication upon the same subject. A communication from the Oswego County Society took the opposite view.

The New Code.

Dr. Squibb, of Brooklyn, offered the following resolutions:

WHEREAS, The Special Committee on The Code of Ethics, in its report at the last annual meeting, recommended a change in one part of the code which was more in the nature of a revolution than a revision, and therefore, may be more radical than was expected or desired by the constituency of this society; and

Whereas, That report was adopted at a session wherein only fifty-two members voted in the affirmative, and thus legislated for the entire profession of the State on a subject of vital importance, in a direction which may not have been anticipated or desired by the profession at large; therefore, be it

Resolved, That all the action taken at the annual meeting of 1882, in regard to changing the Code of Ethics, be repealed, leaving the Code to stand as it was before such action was taken.

Resolved, That a new Special Committee of five be nominated by the Nominating Committee of the Society, and be appointed by the Society to review the Code of Ethics, and to report at the annual meeting of 1884 any changes in the Code that may be deemed advisable.

Resolved, That the report of this Committee be discussed at the meeting of 1884, and be then laid over for final action at the meeting of 1885.

This was made the order of business for the evening session.

Dr. Piffard then read a paper on "*The Pathology and Treatment of Acne*," which he considers to be not primarily an affection of the skin, but dependent upon disease of other organs. The principal causes he enumerated, as masturbation, gastrointestinal disorders, amenorrhœa and uterine disease and certain conditions of blood. The rational treatment is to remove the cause.

A paper on "*Puerperal Eclampsia, and its Management by Induction of Premature Labor*," was read by title by Dr. W. W. Potter, of Buffalo, as was also one by Dr. C. R. Agnew, of New York, on "*The Dangers of Specialties in Medicine*."

"*Removal of Foreign Bodies from the Ear*," was the title of a paper by Dr. Samuel Sexton, of New York. If the patient is difficult to control, etherization may be required. The syringe should be used cautiously. He exhibited an instrument devised by himself for the purpose of seizing foreign bodies; it is like a probe, with a ring at each extremity, which is inserted behind the foreign body and withdrawn. This paper gave rise to considerable discussion.

Dr. W. B. Chase followed, his subject being "*Hot Water as a Hemostatic*," which he highly recommends in surgical as well as obstetrical cases; it does not interfere with primary union.

Dr. C. R. Agnew read his report as delegate to the American Medical Association. He stated that his credentials were refused, and that he was not admitted as a delegate. He received, however, many congratulations from members upon the stand taken by the New York State Medical Society.

At the Afternoon Session Dr. George H. Fox, of New York, read a paper on the treatment of "*Chronic Urticaria*," in which he spoke first of the disease as commonly due to functional disturbance of the abdominal viscera, combined with an abnormal condition of the sympathetic nervous system. To effect a cure we must always depend upon internal medication. An important class are those remedies which tend to eliminate from the blood imperfectly oxygenated material. Bicarbonate of soda, $\mathfrak{z}$ ss., in carbonic acid water, half an hour before each meal. Colchicum is also a valuable agent, at the same time abstaining from meat.

Another important class of remedies are those which allay irritation of the gastro-intestinal tract, such as rhubarb, with occasional resort to mineral water. Bismuth, in some cases of gastric irritation, has proved exceedingly beneficial. Sulphurous acid, in drachm doses, three times a day in sweetened water, has proved especially efficacious.

A third class of remedies are those which act mainly upon the nervous system, such as quinia, arsenic, etc. Special reference was made to salicylic acid, balsam of copaiba, ergot, nettle-tea, etc.

The conclusion was that the treatment is largely empirical and highly unsatisfactory. The apparent value of drugs has been based partly upon careless observations, and partly upon the fact that the eruption often disappears suddenly without any treatment whatever.

The successful treatment must depend upon a knowledge of its etiology, and a diligent study of the causes of the disease will produce results

more conducive to its cure than blind experimentation with remedies.

The paper was discussed by Dr. Rochester, of Buffalo, who spoke of an emetic of ipecac as especially serviceable in the treatment of acute urticaria, and also of some chronic cases of the affection.

Dr. J. O. Roe, of Rochester, read a paper on "The Pathology and Radical Cure of Hay Fever," in which he announced the following conclusions:

First.—Hay fever is an affection not confined to any age or sex, and is not caused by the pollen of flowers or grasses, or by dust or irritating substances alone.

Second.—In some persons, the nasal mucous membrane is very susceptible to certain floating irritants, while in others it is not.

Third.—This peculiar hyperesthesia is caused by a diseased condition of the erectile tissue in the nasal passage.

Fourth.—The systemic effects in hay fever, viz., the lung, laryngeal, and other troubles, are all reflex in character, and are due to the local disturbance in the nose.

Fifth.—Treatment during an attack can only be palliative. The patient had better go where the floating irritating particles do not exist.

Sixth.—Curative measures should be attempted during the intervals of the attack. These curative measures consist in the entire removal of the diseased tissue.

Dr. W. F. Mittendorf, of New York, followed with a paper on "A New Method of Applying Remedies to the Eye."

The method consisted in the use of impalpable powders, made of gum arabic, with a very small quantity of sugar of milk, and containing the alkaloid to be used. The advantages claimed were that the preparations kept for an indefinite time unimpaired, and the quantity put into the eye could be regulated precisely. The disadvantages attending the use of aqueous solutions, such as formative fungi, which changed the strength of the solution; of vaseline, which in many instances simply suspended, and did not dissolve the agent used, etc. The powder is to be applied after the ordinary manner of applying calomel, from a camel's hair brush.

Dr. David Webster read a paper on "Syphilitic Disease of the Labyrinth," which was illustrated by two cases.

Dr. Orin D. Pomeroy read a paper entitled "Syphilitic Disease of the Middle Ear, Labyrinth, and Acoustic Nerve." The writer discussed the subject of the inflammation of these parts together, because their differentiation clinically was not often possible. The symptoms were enumerated, and consisted of deafness, vertigo, tinnitus, often facial paralysis, etc. Various accompanying troubles were mentioned. As to the pathology, it was thought that the middle ear was oftenest involved. The points in diagnosis and treatment were given.

Dr. Gruening read a paper on "The Infusion of Liquorice Bean in Acute Panmus." The formula for making the infusion is as follows: Take thirty-six beans, pulverized, place in 500 grammes cold water for twenty-four hours, then add 500 grammes of hot water, and filter immediately after cooling. Brush it three times a day on

the lids; it produces, in a few days, a decided croupous or purulent inflammation. When the fresh beans are used, the results are so brilliantly successful, that the patients are discharged, cured, in ten days.

Dr. Elsberg gave a demonstration of the use of the tongue spatula, and exhibited his instrument, first presented to the Society nineteen years ago. He claimed that the tongue should be pressed from before backward, and from below upwards—just the reverse of the ordinary practice.

Dr. David Little reported a successful case of ovariectomy without antiseptic treatment other than cleanliness and plenty of fresh air.

At the evening session Dr. Squibbs' resolution concerning the code was brought up and defeated.

Dr. J. G. Adams, of New York, read the following protest:

"As a delegate from the New York Academy of Medicine, I beg leave to report my protest against the recent action of the Society of the State of New York in regard to the Code of Ethics; and I charge that the Society, by its action in this matter, has assumed an attitude and adopted a policy in direct and open hostility to the honor as well as the best interests of the medical profession.

(Signed), "J. G. ADAMS."

The Association then adjourned.

WEDNESDAY.

The history of the successful attempt to provide a hospital for scarlet fever in New York City was given.

Dr. Paul F. Mundé read a paper on "The Etiology and Treatment of Certain Forms of Non-puerperal Uterine Hemorrhage."

In using the word hemorrhage, he wished to limit it to bleeding either during or between the menstrual flows.

1. It may be caused by simple erosion of the surface of the neck of the uterus. The diagnosis can only be made with the speculum. The cervix is seen to be roughened, red, and easily bleeding. He recommended exposure of the cervix with speculum, wiping it dry, and the use of nitrate of silver (3j to 3j) thoroughly applied, and dry iodoform applied upon a pledget of lint. The tampon should be kept in for 24 hours, and then reapplied every day, or every other day, and be followed by injections of sulphate of zinc. Sometimes he uses caustics, or the actual cautery; pyroligneous acid, chromic acid; a surgical operation has been recommended by Emmet, consisting of paring the surface, and stitching the edges together.

2. Slight lacerations of cervix often bleed from touch, coition, or even in walking. Treatment consists in snipping off the granulations with scissors, and cauterizing the base with nitric acid. Trachelorrhaphy is required in gaping lacerations.

3. Chronic subinvolution is a very common cause of bleeding, both inter-menstrual and menstrual. He has been very successful by applying Churchill's tincture of iodine, and internally pills of strychnine, ergot, and iron. Hot water injections are often valuable; galvanism is sometimes useful.

4. A prolonged bleeding may result from the retention of menstrual blood by a pin-hole external os, with dilated cervical canal, and second-

arily from retroflexion. The treatment is by enlarging the external os by cervical incision, and trimming off the edges, making a funnel-shaped os, when the bleeding will cease.

Dr. H. D. Didama, of Syracuse, said: "Believing that the so-called new Code of Ethics is opposed to the opinions of the vast majority of the medical profession throughout the world, as expressed in the action of county, State, and national associations, and in discussions in medical journals; and believing, also, that this so-called code, by removing wholesome restraints, encourages a spirit of lawlessness and sanctions fraud, that it is hurtful, not only to the profession, but to the public, that its adoption sent a thrill of joy through the heart of every quack in the land, and gave pain to the wisest and best of our associates in the regular profession; and believing that its repeal can be secured by concerted action of the friends of honesty and good order, I offer the following amendment to the by-laws.

"Resolved, That all action taken at the annual meeting of 1882 in regard to changing the Code of Ethics be repealed, leaving the Code to stand as it was before such action was taken."

Dr. Wey moved that the matter lie on the table, as the question was already covered by the resolution offered last evening.

Dr. Roosa denounced the resolution, and stigmatized Dr. Didama's remarks as an insult to the majority of this Association, and hoped that the motion would be laid on the table.

Dr. Didama stated that he had expressed his private opinion, but he believed that he also expressed the opinion of the majority of the profession of this State, and of the Union, and of the world. He claimed his constitutional right to present an amendment to the By-Laws.

The point of order was made that no motion was before the meeting, the author of the resolution consenting to allow it to lie over until next year.

Dr. H. Knapp, of New York, read a report on the eighth series of "*One Hundred Cataract Operations.*"

The results were that among one hundred cases there were ninety good results, seven moderate results, two failures, and one case not recorded, as the patient died of hæmaturia. The method of operating was Graefe's modified linear.

Dr. Roosa read a paper on "*Some of the Dangers of the Injudicious Use of Quinine.*"

In a paper read before the American Neurological Association, in 1874, the author called attention to some possible dangers to the organ of hearing from the injudicious use of quinine. From a series of experiments upon animals, undertaken in conjunction with Dr. Hammond, he had found congestion of the internal ear and injection of the optic papilla. In some there was also evidence of retinitis. There is a special danger in those cases where hyperæmia of the eye or ear already exists. He wished to call special attention to this danger in the treatment of pyæmia. He had, with Dr. Ely, treated such cases without quinine, with success. He deplored the popular use of quinine for slight reasons, as, for instance, on no other provocation than merely an aggravated cold. He was behind no one in his appreciation of quinine in proper conditions, such as an intermittent fever

or neuralgia; but he wished to recall to the attention of the profession this possible danger to the organ of hearing from the ordinary doses. Pyæmia is precisely the morbid condition in which quinine should not be given, for it is essential that there be no obstruction of the emunctories, and quinine just favors this obstruction. Again in aggravated colds, it is positively harmful by increasing hyperæmia of the delicate organs of hearing. He recommended the anodyne treatment and confinement of the patient in a warm room, instead of relying upon quinine, which increases tinnitus and general distress. In malarial cases proper he believed that the morbid poison would warrant a slightly increased danger to the organ of hearing. It is true that quinine reduces temperature, but some practitioners aim particularly at reducing temperature in all cases of fever, without regard to the risk to the patient of inducing sudden collapse. In conclusion, he thought that popular use of a powerful remedy can usually be traced to careless practice in the hands of physicians.

Dr. H. W. Williams, of Boston, then made some remarks on "*Erysipelas as extending into the Orbit.*"

He had seen four cases of orbital cellulitis resulting from facial erysipelas, and had never met with a case of this kind until two years ago, nor had any been brought to his notice in literature until after he had seen his first case. The symptoms were pain, projection of the eyeball directly forward rather than to one side, pale condition of the fundus, sensation of fullness, great engorgement of the tissues, swollen lids, chemosis of the eyeball. The treatment recommended was early evacuation of the pus, and this he did in all his cases by means of deep punctures.

Dr. Daniel Lewis, of New York, presented a paper on "*The Development of Cancer from Non-Malignant Disease,*" which was read by title.

Dr. Robert Newman read a paper entitled, "*The Use of Suppositories of Gelatine for Local Medication.*"

The speaker had used cocoa butter and various other substances, but with no good result. Two years ago he began to use bougies of gelatine, and with great success. The speaker showed suppositories of this material for the urethra, rectum, nose, vagina, sinuses, etc.

Special attention was called to the urethral bougies. Their advantages lay in being neat in appearance, soft, elastic, flexible, not easily broken, and slowly dissolved. They contained the medicines equally dissolved and distributed. They are not injured by time or temperature.

The best time to introduce them was at night, and not in the daytime. They had better be moistened with water. In order to keep them in, apply a small piece of cotton at the urethral orifice, and over the latter a bit of adhesive plaster. They are to be used *only* when the urethra is acutely inflamed, and will not tolerate anything.

A number of cases were reported. In prostatitis great care must be used; ten or twelve bougies will generally be sufficient.

Dr. Pooley, of New York, read a paper on "*Rupture of the Choroid.*" A number of cases were related illustrating this trouble. The patient's history, with distorted or more or less loss of vision, and the ophthalmoscopic appearances of a crescentic white patch with concavity toward the optic disk, revealed the disease.

Dr. Frederick Hyde, of Cortland, read a paper entitled, "*When Shall the Trepine be Used in Fracture of the Skull.*" The general tenor of the paper was in favor of a non-conservative treatment of cranial fractures. The writer especially urged the use of the trephine in cases of fracture, even when symptoms of pressure were not present.

Dr. T. H. Squire, of Elmira, read a paper on "*Some Points in Respect to Ovariectomy.*" The first was with regard to the proper form of trocar. The speaker thought that a plain tube with a slot half an inch from the extremity would be an improvement on that generally used. The inner canula might often be dispensed with.

The second point was as to the time when ovariectomy should be performed. There used to be a belief that the operation should be delayed. The speaker thought that the tendency now was to perform it as early as possible. A course of preparatory treatment would always be needed.

Dr. Squire also gave the history of a case of "*Vesical Calculus*" occurring in a girl seventeen years of age. It was removed through the urethra, which had had been fully dilated. The nucleus of the stone was some foreign body, like a pin or needle, which had been left in the bladder.

Dr. L. E. Felton, of Potsdam, then read a paper advocating "*The Use of Lactic Acid in Diabetes Mellitus.*"

He reported the case of a young man, aged twenty-two years, who was passing three gallons of urine, containing large quantities of sugar, sp. grav. 1.040. Strictly meat diet was ordered; lactic acid (one drachm and a half daily) and five pounds of flesh daily. The patient was kept under treatment for four months, and recovered entirely, the diet being gradually extended.

Several other cases were appended in which good effects were likewise observed under the use of lactic acid and a strictly sour-milk and meat diet. The cases were all under thirty years of age, and were free from the disease, except when taking food containing sugar. Skimmed milk or sweet milk caused return of glycosuria.

Dr. W. Gillis, of Fort Covington, reported a case of "*Punctured Wound of the Skull Through the Orbit, by the Tine of a Hay-fork, in a Child.*" The tine passed to the depth of nearly four inches into the left orbit. There was facial paralysis, lasting for some months, but afterwards all symptoms disappeared, except that it was impossible to teach him to talk.

Dr. Hopkins reported a case of a woman, 70 years of age, with "*Right Hemiplegia and Absolute Aphasia.*" Intelligence preserved. Afterwards second attack of apoplexy occurred, and the patient died. No autopsy.

In the evening the annual banquet was held, before which the President delivered his annual address, taking for the subject "*Some of the Perils to Life from Preventable Diseases.*"

THURSDAY.

Dr. L. D. Bulkley, of New York, read by title a paper on "*The Management of Some Forms of Eczema.*"

Dr. Howe, of New York, offered an

Amendment to the By-Laws.

Which was laid over for one year, "That the Code of Ethics of the American Medical Association be substituted for the Code adopted by this Society in 1882." He said that then, when our State Society had gained an unquestionable right to representation, that our delegates should be instructed to advocate such modification of the National Code as shall be in accordance with a spirit of greater liberality, or even, if advisable, to urge its entire abolition.

The following officers were elected for the ensuing year:

President.—Alexander Hutchins, M. D., of Brooklyn.

Vice-President.—H. G. P. Spencer, M. D., of Watertown.

Secretary.—William Manlius Smith, M. D., of Syracuse.

Treasurer.—Charles H. Porter, M. D., of Albany.

EDITORIAL DEPARTMENT.

PERISCOPE.

Feigned Skin Disease.

Dr. T. Colcott Fox records the following instructive case in the *Lancet*, December 30, 1882. A S—, aged nearly sixteen years, a furtive-looking general servant in London, presented herself at the Skin Department of the North-west London Hospital on the 28th of November. The catamenia commenced at the age of thirteen, but had since been irregular, and for the past year absent. She was fairly well nourished, but pasty-looking, and her finger-nails were markedly grooved. She applied on account of three excoriated patches

which appeared on November 21st, close together on the front of her left leg, and had, she stated, given her great pain. and caused her to lie awake sobbing at night, so that her mistress had no longer the heart to keep her at work. The suggestion had been made that the sores were caused by the dye from her black stockings, and the girl said that she had dressed the places with "Moore's ointment." One sore was perfectly oval, another nearly heart-shaped, and the third triangular, with a horn at each angle at the base. The patches measured about $1\frac{1}{4}$ in. by $1\frac{1}{2}$ in. to 2 in., and the long axis was in the direction of the limb; they were simple uniform weeping excoriations, with hardly any attendant inflammation. Sus-

pecting the nature of the lesion, I ordered a simple dressing and a saline aperient, and talked of admitting the girl into the hospital if more sores appeared. On December 5th she returned with a transversely oval sore just above each mamma (a very characteristic site in feigned cases), but not quite symmetrically situated. There were two others above the left ankle-joint, and one on the outside of the right calf, all longitudinally oval simple excoriations, with a well-defined border, except on one sore, where the abrasion was not complete at one end, and only papulation existed, suggesting a cantharides application. There was a dark-brown blood scab on some. She was admitted to the wards. On December 6th a transversely oval patch appeared just below the left mamma; and another, longitudinally oval, covered with a slight scab, on the right hip. The girl, from time to time for twenty-four hours after admission, had prolonged fits of hysterical sobbing. On the 12th a sore appeared on the right shin near the ankle, and another on the right mamma, between the site of a former excoriation and the areola. There was a remarkable uniformity in the size of the patches throughout. As to the agency at work, I never could detect any evidence of the formation of a bulla, and the patches were too superficial for causation by an acid; moreover, repeated examination of the clothes, bedding, etc., at convenient times and unbeknown to the patient, failed to furnish any clue. On the 16th, no more excoriations having appeared, I taxed the girl with producing the eruption artificially, and, after prolonged denials, she confessed that she had done so, partly by her nails, but mostly by continued rubbing with the tops of her fingers. Probably the malingering was not altogether motiveless, and she desired a rest from her household labors. She proved to be very troublesome and disobedient in the ward, and I learnt from her father that she was an incorrigibly bad girl and a constant source of worry. The case is of interest as establishing an agency which has hitherto only been suspected as possible. Whether the skin in these cases is peculiarly sensitive to injury is a point for further investigation.

Syphilitic Inflammation of the Capsule of the Liver.

Dr. Sharkey read the notes of this case before the Pathological Society of London (*British Medical Journal*, January 20, 1883).

The patient was a man who was admitted under the late Dr. Murchison in 1876. He was suffering from diarrhoea, and his liver was much enlarged, reaching to the umbilicus, and presenting a large, faintly-nodulated mass, apparently projecting from the left lobe. In 1878 he was readmitted, suffering from hematemesis, melena, dropsy, and slight jaundice. He died a little later. At the *post mortem* examination the liver was found to weigh 6 lbs. 7 ozs.; the surface was coarsely nodulated, and the whole contour of the organ was distorted; from the capsule inwards for an inch and a half a growth of hard fibrous material extended; this was due to a fibrocellular new growth springing from the capsule, and extending along the lines of Glisson's capsule; in this growth were imbedded small gummata, the

centres of which were caseating. The patient gave a distinct history of alcoholism, but not of syphilis.

Dr. Mahomed inquired whether there were any other signs of syphilis. The drawing shown by Dr. Sharkey did not seem to exhibit anything that might not be found in alcoholic cirrhosis. He referred to a liver, which he had recently removed from a body, where the right lobe was greatly contracted, while the left was large and cirrhotic; he felt great hesitation in classing such a case as this as syphilitic.

Mr. Butlin thought that it was hardly safe to make these small so-called gummata conclusive evidence of syphilis; they might just as probably, from the evidence offered, be attributed to caseation of the products of inflammation.

Dr. T. H. Green inquired whether fibroid disease of the liver, extending inwards from the capsule, was ever found in any cases where syphilis was not an element in the causation. He believed that, as a rule, there was not much difficulty in coming to a decided opinion with regard to the nature of gummata.

Dr. Norman Moore thought there were no visceral lesions, other than large gummata, which, by themselves, so distinctly pointed to syphilis, that it was, in every case, safe to speak positively. He thought that where a thickening of the capsule extended into the liver substance, that was good evidence of the existence of syphilis; still he had recently seen a case which contravened this generally held opinion.

Mr. Roger Williams referred to two cases of syphilitic disease of the liver which he had seen.

Dr. Samuel West believed that cases of chronic fibroid growth, extending from the capsule into the liver, and due to peritonitis, were not uncommon; but that cases of a syphilitic nature had certain well recognized characteristics.

Dr. Goodhart thought that, in the vast majority of cases, it was easy to recognize syphilitic disease of the liver, the changes being so characteristic.

Dr. Coupland agreed with Dr. Goodhart. He had seen several cases where the lesion was limited to a capsulitis, quite distinct from ordinary cirrhosis; in such cases, gummata were often not found. He wished to inquire whether the testes had been examined.

Dr. Buzzard inquired whether the eyes had been examined with the ophthalmoscope.

Mr. Thorburn inquired whether the penis had been searched for traces of old disease.

Dr. Sharkey said that there were no other evidences of syphilis, beyond those which had been described in the liver. He thought, however, that the small gummata were perfectly characteristic. Neither the penis nor the testes were examined. The changes in the eye were nothing more than small retinal hemorrhages, and not at all characteristic of syphilis.

Convallaria Majalis in Heart Disease.

The *Medical Times and Gazette*, January 6, 1883, says: "In three recent numbers (44 to 46) of the *Wiener Medizinische Wochenschrift*, Dr. B. Stiller has reported twenty-one cases of heart disease

treated by a Russian remedy which rejoices in the name of *Convallaria majalis*. The credentials with which Bogojawlensky sent the drug forth to the medical world were—that it affected animals in a manner analogous to digitalis; that it made an irregular pulse regular, diminished dyspnoea, and increased the amount of urine; and that it did not suffer from the failings of digitalis in the way of cumulative effects. Another set of observers, Böttkin and Troitzky, confirmed these claims, and further lauded the use of the drug in cases of nervous palpitation. At the end of last year other Russian physicians corroborated previous accounts, and, moreover, praised the remedy as of value in exophthalmic goitre. It would appear that convallaria contains two glucosides, one of which was pointed out as a heart poison by Marmé in 1867, and this, given in small doses to warm-blooded creatures, prolonged the cardiac stroke without raising the blood-pressure. It is further stated that the plant was formerly employed as a diuretic, and popularly also in epilepsy and neuroses generally.

In the course of the present year, Germain Sée (*Tribune Médicale*, No. 16) employed a watery extract, in experiments on animals and clinically, instead of the usual infusion; according to him the watery extract regulates the frequency and rhythm of the heart-beats, increases the strength of the contractions, raises the blood-pressure, lessens the shortness of breath, and causes polyuria. He prefers the drug to the digitalis because it does not produce cumulative effects, does not upset the stomach, and is not hampered by contra-indications. Stiller used the infusion, and observed no unpleasant symptoms, *e. g.*, nausea, vomiting, diarrhoea. The taste is bitter, but not disagreeable, and at all events, nicer than digitalis. Seventeen persons were treated by Stiller, some for relapses, making a total of 21 cases, 15 of whom were males; the ages varied from eleven to seventy years, and the diseases were 4 cases of mitral insufficiency with aortic regurgitation, 1 of pure mitral regurgitation, 4 of regurgitant and stenotic mitral disease, 4 of mitral stenosis, 5 of weak heart and dilated left ventricle, and, lastly, 2 cases of Graves's disease—altogether a motley group of cardiac diseases. Out of the 21 cases, 17 gave absolutely negative results with convallaria—there was not the least influence on the frequency or rhythm of the heart's action, etc. Some of these cases proving intractable to convallaria were subsequently benefited by digitalis; two individuals experienced a certain degree of the diuretic effect of the new drug without any other of the vaunted phenomena, not even the dropsy being diminished; two patients underwent decided improvement in most of the cardiac symptoms during the use of the new medicine, but these cannot outweigh the large balance of negative results. Stiller, therefore, is unable to echo the praises of the liliaceous drug sounded in Petersburg and Paris. The explanation of the conflicting experiences may be found in the quality of the medicament, or in the mode of its preparation, on which features we are unable to give further particulars owing to absence of such information in the papers to which we have referred.

The Pathology of Whooping-Cough.

At a late meeting of the Medical Society of London (*Lancet*), Mr. Dolan read an abstract of his essay on whooping-cough, to which had been awarded the Fothergillian medal of the Society. Dealing with some points of its pathogeny, he expressed his dissent from the view of Guéneau de Mussy, that the malady was a bronchial adenopathy, its chief symptom being induced by pressure on the vagus by the enlarged glands, and showed that the glandular enlargement was not always present in pertussis, and further that the glands may be swollen without producing the characteristic cough. The disease, indeed, bore much resemblance to those diseases, the causes of which are now believed to be minute organisms or fungi. Its highly contagious nature, period of incubation, effervescence and defervescence, its regular course, and the immunity from subsequent attacks, were grounds of analogy determining the place of pertussis in the group of diseases caused by protophytic fungi. The attempt by Linnæus to prove that all diseases were produced by animalcula, or had an insect origin, foreshadowed the conclusions now arrived at by the discoveries of Pasteur. In 1867, Poulet found bacteria in the sputa of pertussoid patients, and Letzerich had induced whooping-cough in rabbits by inoculating the trachea with sputa from the human subject. The author had repeated these experiments, and found that whilst inoculation with the blood of whooping-cough patients was without effect, that of sputa and other secretions caused death. He had found also on microscopic examination of sputa ordinary bacteroid forms, and a microbe resembling the spirochæte plicatis of Cohn. The application of special methods of staining, as employed in the detection of bacillus tuberculosis, would no doubt reveal the special microbe of pertussis. Admitting the fungoid nature of pertussis, its contagious property was easily explained by germs being thrown off into the air and received into the body, setting up constitutional disturbance, and subsequently attacking the pulmonary epithelium, giving rise to all the phenomena of pertussis. No pathognomonic lesions could be detected on post-mortem examination, for the simple reason that whooping-cough was rarely fatal; death resulted from complications, which were very numerous. As to glycosuria in whooping-cough, he had found it present in fourteen out of fifty cases. Turning to the question of treatment, he pointed out the necessity for measures of isolation in preventing the spread of the disease, for the enforcement of which measures the co-operation of all classes of the community was needed; and although the course of the disease could not be controlled by treatment, the patient could be placed in the most favorable circumstances toward recovery; certain painful and prominent sources of trouble could be relieved and complications guarded against, so as to assist nature in her efforts to throw off the disease. There was no panacea or specific remedy, but if the dependence of whooping-cough upon a specific virus be the true explanation of its pathogeny, the lines on which its rational treatment and prophylaxis were to be pursued became clearer and more hopeful.

Rupture of Uterus Probably Due to Ergot.

The rupture of the uterus from ergot, with death occurring several hours later, is so rare that the case reported in the *Boston Medical and Surgical Journal*, February 8, 1883, by Dr. E. M. Buckingham, is worthy of note. The woman, a multipara, was given two teaspoonfuls of fluid extract of ergot, with the effect of causing, for a time, very severe pains, which suddenly ceased. From eleven in the morning until seven in the evening there were no pains. She seemed in good condition. She was etherized, and as one hand and a pulseless cord had descended into the vagina, it was decided to turn and deliver. The head stuck behind the pubic arch, and while efforts were being made to extricate, the woman suddenly collapsed. The ether had never been pushed to snoring. All efforts to resuscitate were unavailing, and she died. The head was removed by forceps. The placenta was removed, and he felt a tear through the muscular wall of the uterus, to the right of the median line, and near where the placenta had been. This was large enough to insert the hand, and there was a smaller tear in the peritoneum behind it.

Rupture must have occurred either as a result of the forced pains caused by ergot, from the use of forceps, or from turning. He does not believe that it was done during turning, because the uterus was then lax, and there was no resistance until the head was under the pubic arch, and because the accident can be otherwise, and he thinks better explained; neither does he think it was done by the manipulation of the previous attendant, for although trying to apply forceps with the patient tossing about the bed may be dangerous, yet this was after the occurrence of a pretty well recognized symptom of rupture, that is, very severe pain, pain that was complained of hours later by a woman who had borne several children, and which suddenly ceased.

He supposes that the emptying the uterus in this case either increased the tear or caused hemorrhage into the peritoneum, either of which would explain the sudden failure.

Uræmic Psychosis.

Dr. Edward T. Bruen reports a case which he calls *Uræmic Psychosis*. A man between 40 and 50, in whom the diagnosis of interstitial nephritis had been established, and in whom the ordinary cardiac and arterial lesions attendant upon this disease were moderately well marked, together with the usual symptoms found in such cases, but without any mental disturbance, awakened one morning in a state of confused intellect. In a few hours intense excitement and wild hallucinations manifested themselves. The skin was bathed in sweat, pupils immobile, pulse slow, and respiration only ten per minute. At times the excitement tended to deepen into stupor and coma, but soon the psychical disturbances reasserted themselves. This state lasted three days, when the patient recovered his ordinary condition, and was unaware that anything unusual had transpired. The chief item in the treatment consisted in the free use of *jaborandi*, until copious diaphoresis was produced, which was not considered contra-indicated by the already

existing leaky skin, produced, as it evidently was, by repletion of cutaneous vessels, and hence was a transudation, and unable to eliminate the products of retrograde tissue change. that the direct stimulation of the sweat-glands by the remedy produced.—*Med. Times*, January 27, 1883.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—The Gulf Coast of Florida has not received the attention its climatic character merits as a health resort for invalids during the winter months. Years ago we passed a month or two there, and can therefore endorse from our own recollections the very favorable commendations of it lately published by Dr. R. J. Levis, of this city. The following extract gives his views:

Of the extended seaboard of Florida, the Gulf Coast stretches over seven hundred miles. The climate of this coast has, in my opinion, more of the essentials of a good winter resort for invalids than any other of which I know. I make this statement after some personal experience over a large extent of the coast, from much conference with invalids who have happily tested its merits, and from a comparison with the thermometric and hygrometric records of many of the various popular health resorts of the world. The west, or Gulf, coast of Florida has a temperature more mild, equable and dry than that of the corresponding Atlantic border. As compared with that of the much-frequented region of the St. John's river, in the winter season it is free from malarious influences, fogs are unknown, and the opportunities and inducements for an out-door life are far greater.

Dr. Levis' article has been reprinted with a map of the Gulf Coast, and may be had gratuitously by forwarding a two-cent stamp to this office.

—A paper by Dr. A. N. Blodgett, of Boston, on the management of chronic inebriates and insane drunkards, argues in favor of absolute abstinence, the separation of dipsomaniacs from others, and condemns as nearly useless all existing institutions for inebriates. He appears to us to be altogether too positive in his charges of inefficiency against the last mentioned.

—A little book written and distributed by Jas. I. Fellows, London and New York (48 Vesey street), on the use of the syrup of the hypophosphites in some affections of the organs of respiration, is worthy the attention of those who would prescribe this remedial agent. The book is distributed gratuitously to applicants.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

LEAGUE ISLAND NAVY YARD.

League Island, it may not be known to everybody, is a bit of swamp land at the junction of the Delaware and Schuylkill rivers, which the United States, in its wisdom, selected some years ago as the site of a navy yard.

What advantages it possessed for this purpose have never been clearly ascertained. What disadvantages, on the other hand, it presents and always has presented, have been abundantly clear to all concerned, and have been brought into still stronger light by the full and accurate report of Surgeon G. H. COOKE, which has just appeared in the *Report of the Surgeon-General, U. S. Navy.*

The highest natural level of the island was originally not quite three feet above low water mark; but the slime and mud, dredged from the "Back Channel," has been heaped upon it in places so that now the greatest height is ten feet above low-tide level. Formerly the island was drained by intersecting ditches, but now, owing to "lack of funds," these are neglected, and in summer form stagnant, slimy pools, full of decaying organic matter, animal, vegetable, and fecal.

On digging anywhere in the island, water—or a foul fluid so-called—is reached at the depth of about eighteen inches. Consequently there is no drainage, and cannot be any. The privies and cess-pools are mere holes in the ground, whose contents permeate the surrounding boggy soil, and saturate it with their poison.

On one side of the island the sluggish waters of the Schuylkill carry back and forward with the tide the refuse of the city abattoir, large masses of sewage, waste products of gas and coal oil works, and other impurities, which sink in its waters and form a stratum of about one inch yearly of black, fetid mud.

On the mainland immediately adjacent to the island there are numerous ranges of hog-pens, to which are brought immense quantities of offal and garbage from the city. The land between them is principally used for truck patches, which are manured with night-soil just as it is brought from the privies of the city. Bone-boiling, fat-render-

ing, and poudrette establishments are scattered here and there. Pools and swamps covered with green slime and filled with dead animals and decaying weeds are met with throughout this low ground called "The Neck."

"It is a continual subject of remark," says Dr. COOKE, "on the part of persons approaching the Neck after sunset, from the built-up portions of the city, that as soon as the open fields are reached a cold, damp, heavy atmosphere strikes a chill to the system, and a mist hangs low over the land; which mist increases in density and depth as League Island is approached."

No wonder that the Report we are quoting from goes on to say that League Island "presents, in an eminent degree, all the conditions necessary to develop to its fullest intensity the malarial poison." No wonder that the sick report shows a constant and heavy percentage of malarial cases, and a general deterioration in the health of the men and officers there stationed.

Can these unhealthy conditions be remedied?

Dr. COOKE answers that the difficulties are "almost insuperable," and points out that the nature of the soil, its low level, its thorough infiltration with organic matter, and the utterly insalubrious surroundings, can scarcely be overcome. Even the expenditure of "millions of money and years of labor" would fail, in his opinion, to insure a positive and permanent salubrity to this ill-chosen locality.

What is the inference from all this?

It is, that the selection of League Island as the site of a navy yard was a piece of gross ignorance, or heartless political jobbery, which would sacrifice the life and health of thousands of men to the profit of a few interested persons. The hundreds of thousands—millions, probably—that have been spent there, have been worse than wasted. Without more ado, the site should be given up, and the navy yard moved altogether away from this city, unless we can show a better site for it. We have no moral right as a nation to condemn the officers and men of our navy to such a pest-spot as League Island.

THE COLLECTIVE INVESTIGATION OF DISEASE.

This subject, which at the present time seems so attractive to the profession of England, is one well worthy of our most serious consideration. Two eminent Englishmen, Sir James Paget and Sir William Gull, recently addressed their conferees on this matter, the latter of whom said, "There are many 'every-day' diseases which have not as yet been submitted to a scientific inquiry." He appealed, especially to general practitioners, for help in this research, and here he struck the true key-note. For, as he justly remarked, "hospital practice is worth very little without a good admixture of general practice to correct it. Men with hospital appointments are apt to see only the severe cases, isolated cases, and are unable to get at early and accurate histories." The importance of family history, with a view to trace, if possible, the variations of the same dyscrasia, in different individuals of the same family, and at different ages, was insisted upon. This is very often impossible in hospital practice. How is it that some persons are more susceptible to the influence of poisons than others?—had their predecessors, so to speak, been vaccinated, and thus acquired for their descendants an immunity which others, not so vaccinated, did not enjoy? Thus the peculiar fever which visitors to Rome so frequently get is not endemic among the stationary population. Sir James Paget stated that Darwin had made his name immortal as much from the manner in which he had worked, as from the matter at which he worked. He feared that a great deal of work was lost because no records had been kept; and records were not kept, often, because the matter seemed too trivial for record. This is a vital mistake: with but a few isolated exceptions, it is not the rule in our profession to keep records of our trifling cases; and yet, as distinguished authority tells us, and experience amply teaches, it is from the aggregation of certain phenomena presented by observation of these seemingly trivial cases, that we are enabled to formulate definite laws.

By the aid of a little system, it would not add much to your labor to make a full record of the

family history and symptoms of each case you are called to attend.

If you were to faithfully do this, and at the end of six months review your records, you would surely find sufficient of interest to form the material for a paper to be read before your medical society, and by the aggregation of such experiences, and their comparison, much light would be thrown on our studies. Do not forget this suggestion, but try it, and see if you do not find it to work admirably.

THE NEW ANATOMY ACT.

The bill which has just been presented to the Legislature, to regulate the supply of dead bodies for dissection, is one eminently worthy of the support of the profession and of all who are interested in human welfare.

It provides for the receipt of all the unclaimed dead from all the counties of the State, who would otherwise have to be buried at the public expense, by a committee, who shall distribute them pro rata among the colleges and schools of anatomy containing twenty-five students or more.

This committee will be under bonds to faithfully and honestly do their duty, and not to traffic in nor to send without the State the bodies so procured.

Anatomy is the universally recognized *sine qua non* foundation of all medical science, without a knowledge of which a competent physician is an impossibility.

Dissection, likewise, it is universally conceded, is the only true way to learn anatomy; that derived from books being nearly worthless, unless supplemented by the practical acquaintance with the subject which dissection alone can impart; and finally, to dissect, students must have material. So well do students realize the importance of dissection that they *will* procure the material for it, by fair means, if possible; if not—well, we may have numerous repetitions of the newspaper sensation of last fall. Medical students and medical teachers are as a rule just as law-abiding as any other class of citizens, and it is not their wish to break the laws: but they must have material.

If, perchance, there may be some solitary individual opposed to this act, let him pause and realize that if such legislation is not framed, the temptation to crime is great; for, to repeat, the history of our profession teaches us, in unmistakable terms, that anatomy *must* be studied in the dissecting-room, by the side of the dead body. Let us trust that our legislators will not put a premium upon grave robbery by failing to pass this bill; but that, realizing its paramount importance, they will rush it through with all possible dispatch.

THE SUPERVISION AND CONTROL OF LUNATIC ASYLUMS.

The Special Commission, appointed last May, by Governor Hoyt, to examine into the present system for the care of the insane of the State, etc., has made a report and prepared a bill, which is now before the legislature for action.

To those interested in the subject, we would suggest careful perusal of the bill, a copy of which can be obtained by application to any of the Commission.

Prepared by fully competent gentlemen, we can only find one section to which we can take exception; and this, constituting as it does the *greatest* abuse of the present system, is the portion calling most loudly for change.

"No person shall be received as a patient, or for detention, into any house or place where more than one insane person is detained, or into any house or place where one or more insane persons are detained, for compensation without a certificate signed by at least *two physicians*, who have been actually in the practice of medicine for at least five years, both of whom shall certify that they have examined separately the person alleged to be insane, and after such examination had, do verily believe that the person is insane, and that the disease is of a character which in their opinion requires that the person should be placed in a hospital or other establishment where the insane are detained for care and treatment, and that they are not related by blood or marriage to the person alleged to be insane, nor in any way connected as a medical attendant or otherwise with the hospital or other establishment in which it is proposed to place such person."

We do not fear contradiction when we make the unsavory statement that it would not be an impossible thing to *purchase* the opinions of two *reputable* physicians—of University or Jefferson

graduates; and herein lies the faultiness, and the only one, of this bill.

As an offset to this possible contingency, it is provided—

“In case the said medical attendant is of the opinion that a detention is not necessary for the benefit of the patient, he shall notify the person or persons at whose instance the patient is detained, and unless such person shall, within twenty-four hours, exhibit satisfactory proof of such necessity, the patient shall be discharged from the house and conveyed to the nearest place where a public conveyance can be obtained by him.

“At the time of such examination, the medical attendant shall himself cause the patient distinctly to understand, if he or she is capable of doing so, that if he or she desires to see or otherwise communicate with any person or persons, means will be provided for such interview or communication; and said attendant shall personally see that proper means are taken to communicate this fact to the person or persons indicated by the patient, and any person or persons whom the patient may then desire to see shall be permitted to have a full and unrestrained interview with the patient;” and

“During the detention of any person as insane, any medical practitioner designated by him or by any member of his family, or ‘near friend,’ with the sanction of a judge of a court of record of the county in which such insane person resided at the time of his removal and detention, shall be permitted at all reasonable hours to visit and examine the patient, and such medical attendant shall, unless objected to by the patient, be permitted, by request of his or her family, or ‘near friend,’ and with the consent of the physician-in-chief of the establishment, to attend the patient for all maladies, other than insanity, in the same manner as if the patient were in his own home.

“All persons detained as insane shall, at all times, be furnished with materials for communicating, under seal, with any person without the building, and such communications shall be stamped and mailed daily. Should the patient desire it, all rational communications shall be written at his dictation, and duly mailed to any relative or friend named by the patient.”

On the principle that “possession is nine points of the law,” it is very easy to conceive that when two *reputable* physicians have declared a person insane, any subsequent physician or authority will naturally be, to a certain extent, prejudiced against, unless, on account of personal considerations, he is unduly prejudiced in favor of, the sanity of his *friend*.

Recognizing the dimness of our acquaintance with the border line between sanity and insanity, we realize how difficult it would be to provide against such possible errors, but we would make a suggestion:

If a commission of three physicians should have to pass on the question, we should have a checking influence on the action of the two. If the bill should provide for the permanent establishment of a paid (and well paid) board of three physicians, to pass upon all questions of sanity throughout the State, a certificate from the majority of them being a necessary preliminary to a commitment; and if such Board were appointed by, say the Trustees of the University of Pennsylvania, upon the recommendation of the Provost, we should have the best possible guarantee of integrity in this terrible responsibility of declaring a fellow-being insane.

With this one important exception, we heartily endorse the proposed bill; and with such a modification, urge our readers to use their influence to have it made a law.

NOTES AND COMMENTS.

Tissue Change in Fevers.

We can undoubtedly learn a great deal from the change of tissue, as it proceeds in fevers, by carefully examining the excretions and comparing them with those during health. Usually the excretion of phosphoric acid or its salts is diminished during febrile states, and the view had been adopted that we had to find the source of nitrogen in fevers mainly in the red corpuscles. Dr. Edlessen, who has made this subject a special study (Mitt. d. Vereins, Schlesw. Holst. Aertz., 1882-3), believes, however, that the great diminution of the excretion of phosphoric acid depended especially upon retention, and that the phosphorus was used by the organism in the transient formation of white corpuscles, which is so frequently noted in febrile conditions. With this hypothesis, E. thinks that the waste of muscular tissue in fevers might also be explained: the albuminous substance of the muscular tissue in union with phosphoric acid and potash enters the circulation and is there made use of for the purpose of forming white corpuscles and other, under the circumstances, morbid products. This finds a confirmation in the statement of Dr. Salkowski (*Med. Centralbl.*, 1882, 43, MED. AND SURG. REP., November), that the excretion of potash-salts is greatly diminished in fevers.

We remember that Prof. Gross used to recom-

mend allowing patients suffering from fever to eat anything they seem to have an abnormal appetite for—a longing after—if it was not directly injurious to them. The observations made by Edlessen and Salkowski would explain the fact that so many, if not all, fever patients have a special desire for salty and acid substances; they generally enjoy greatly all mineral waters containing potash or phosphorus, or both, (Apollinaris, Selters, Vichy, etc.,) and lemonade, if made from phosphoric acid, pickled things, salt sardelles, etc. As our appetite is nothing else than a wish expressed by the tissues for nourishment, and reflected through the pneumogastric nerve to the stomach, all such abnormal desires for special kinds of food usually denote a want of such substances by the tissues or a particular part of them. A similar fact happens with pregnant women, who sometimes have a morbid desire to eat brick-dust, chalk or such substances, elementary parts of which go to build up the osseous system of the fœtus. M. once attended a lady who, during her pregnancy, evinced a disturbed nutrition in her teeth, hair, nails and skin. If she was allowed to eat all the chalk she desired, those disturbances soon ceased, but reappeared when her morbid (normal?) appetite for these substances was not satisfied. When not positively harmful, such peculiar desires should always be permitted to be indulged in.

New Remedy for Syphilis.

The *Medical Times and Gazette*, January 6, 1883, says that Prof. Liebreich brought forward, at the last meeting but one of the Berlin Medical Society, a new drug for the treatment of syphilis by the subcutaneous method. This drug rejoices in the name of hydrargyrum formidatum, and is, therefore, merely a different form of the old cure for syphilis. The mode of its preparation was not stated; chemically, it belongs to the amide group, in whose structure the monovalent amidogen (NH_2) plays an important part. Liebreich was led to think of this new preparation from the notion that the ordinary amides of the body, of which urea may be regarded as the principal one, pass out of the organism in an undecomposed state; when, however, an amide is in combination with a metal, decomposition readily occurs, and the metal is reduced and deposited. Liebreich repeated his experiments before the Society, and showed that these conjectures were quite true for the metal mercury. It is supposed, therefore, that the formamide of mercury, after the hypodermic injection, undergoes disintegration; and so the mercury is set free, and is able to exert its

well-known power over the lesions of syphilis. The preparation is easily soluble in water, is of neutral reaction, does not coagulate albumen, is not precipitated by caustic soda, and the presence of mercury can be demonstrated by means of sulphide of potassium. The drug, when injected under the skin, produces its effects very surely and rapidly. This is not regarded as a disadvantage, for the medicine is said to be easily borne, and has never produced salivation in Liebreich's hands. There is very little pain attendant on the injection, which has never excited any inflammation. From a half to a whole of a Pravaz syringe-ful (a one per cent. watery solution) may be injected twice or thrice daily. Liebreich looks on the preparation as the best we yet have for subcutaneous injection.

Acute Catarrh of the Nose.

Notwithstanding acute inflammation of the Schneiderian mucous membrane of the nose is perhaps the most common and frequent ailment human flesh is heir to, in systematic works on medicine or surgery very little is found about it. This may be one of the reasons why it is generally neglected, badly treated, and often lapses into a chronic state. Dr. Scheff has written in the *Wiener Med. Presse* (23, 1882) a rather interesting article on Rhinitis, Koryza. He first mentions all the well-known symptoms of this disease. While not totally denying an inherited disposition to such catarrhs, Scheff contends that such disposition mainly depends upon physiological variations in the architecture of the nasal cavity. He repeats in this respect mainly what Dr. Zuckerhandl has said about it. In some cases the turbinated bones are thicker, and of varying form, so that the natural passages and cavities become smaller, or a greater surface is directly opposed to the air, instead, as it normally should be the case, the air having to take a winding way amongst all the different passages. Concerning therapeutics, Scheff knows nothing new.

In this respect we mention for the benefit of our readers the article of Dr. Gentilhomme (*De l'emploi du Sulfate d'Atropine dans le traitement du Coryza. Union Méd. et Scientifique du Nord-Est*, 1882-5. G. recommends very highly in the treatment of acute nasal catarrh, the sulphate of atropia in doses of a half milligramme—about $\frac{1}{120}$ grain. He reports a number of cases in which the effect of the remedy was very apparent. Especially if there is much watery discharge, the drug seems to be most effective. As there is not much trouble or danger to be feared in the administration of so

small a dose of atropia, it may be well to give his treatment a trial, though we give it for what it may be worth.

Loss of Both Parotid Glands.

Lewis C., æt. 29, contracted chills and fever. When first seen by C. M. Ramsdell, M. D. (*Med. News*, Jan. 13, 1883), temperature was 103°; which was reduced by quinine; three days afterwards his left jaw began to swell, and by noon the whole left side of neck and face was much swollen. The next day the right parotid region commenced swelling, and soon reached an enormous size. Prostration was now great. Patient was placed upon a stimulant, a pyrexial treatment, abscesses were lanced when ripe, three days from commencement of attack. They then pursued the course of an ordinary abscess until the seventh day, when "proud flesh" was found occluding the wound. This was removed, and proved to be the parotid glands almost entire. They were of the same appearance, spongy, with deep sulci, apparently where large vessels or nerves had passed through them. The right gland retained somewhat its natural shape, but the left could be determined alone by its internal structure. No other glands were implicated, nor any burrowing of pus. A month sufficed to complete the cure. Patient complained of having more "heart-burn" than he used to have. His mouth seemed dryer than natural. Steno's duct was closed on the left side; on the right it consisted of a *cul-de-sac* about a fourth of an inch deep. The remaining salivary glands have taken an increased functional activity, and the above conditions are ameliorated.

"This case seems to be unique. Flint says that parotiditis is an occasional complication of typhus and typhoid, and in such cases considerable sloughing of the areolar tissue frequently occurs; but neither he nor any other writer, so far as I know, mentions loss of the gland as a possible result."

Puncture of Gravid Uterus During Ovariectomy.

At a recent meeting of the New York Obstetrical Society, Dr. C. C. Lee related the following case (*New York Medical Journal*, January 27, 1883): A patient, twenty-eight years of age, was sent to the Woman's Hospital by Dr. Hanks, for the removal of an ovarian cyst situated on the right side. The presence of the cyst was supposed to have been the cause of several miscarriages, and, as the patient was then three months pregnant, it was thought likely to prove so again. After making the usual incision for ovariectomy, the ex-

act relation of the tumor to the uterus was ascertained. In turning the patient on her side, preparatory to puncturing the cyst, the latter was let go, and, unknown to Dr. Lee, the uterus took its place, rolling up into the abdominal incision, and was punctured instead. A large trocar penetrated the body of the womb to a depth of about two inches, entering at a point about two inches below the fundus. No fluid escaped when the trocar was withdrawn. The uterine wound was sewed up with carbolized silk, the long pedicle of the ovarian cyst was then ligated, the cyst was removed, and the abdominal wound was closed. Abortion had not occurred, and the patient was doing well. There had been vomiting, which was probably due to the influence of the anæsthetic. It was a noteworthy fact that the pedicle in this case was so long that the tumor, which was developed from the left ovary, lay upon the opposite side, in the region of the right ovary. Dr. Lee thought the silk-worm suture, which was used to close the abdominal wound, possessed no advantages over the carbolized silk ligature. It was much more liable to break, and was less easy to handle.

Gonorrhœal Rheumatism.

The *Medical Times and Gazette* says that Prof. Peter pointed out a case at his clinic (*Gaz. des Hôp.*, June 17,) in illustration of the fact that in the so-called gonorrhœal rheumatism the joint is not the seat of the affection, but the adjoining white tissues or "tenosity"; and that consequently there is no complication from heart disease, while the prognosis is much more favorable. The gonorrhœal discharge exerts no specific effect in producing it, any genital irritation being competent to this, acting through some ill-understood mechanism, as in profuse leucorrhœal discharge, or the sudden arrest of the menses. In this case abundant gonorrhœal discharge was present in a woman, and the left ankle joint seemed to be the seat of an attack of acute rheumatism. This, however, was not the case, and the diagnosis was obtained by the mode of examining the joint. Feeling below the internal malleolus, great pain was produced; but palpation at the external part, or in front, or deeply behind under the tendo Achillis, gave rise to no abnormal sensibility. Returning again to the inner side, and examining methodically, it was found that pain really only existed in the direction of the sheath of the tendons which passed under the malleolus internus—there being therefore only a tenosity, easy to define. It is only very rarely indeed that the joint is implicated.

SPECIAL REPORT.

REPORT OF PROGRESS OF OTOTOLOGY, NO. 2.

Diseases of the Ear in Children.*

The first subject which we will treat of is congenital variations and malformations of the ear, in which "if the osseous meatus is entirely absent, every operation is useless." "As the meatus of children is narrow and usually secretes freely, it is often necessary if the child's hearing is defective before an examination is made, to cleanse the passage in order to get a clear view of the deeper parts; and good illumination by a mirror is of the first importance.

After syringing, it is best to dry out the passage. It should be understood that every child, in the latter part of intra-uterine and the first part of extra-uterine life, possesses no free meatus, the passage being closed by epidermal product—the drum-membrane instead of being horizontal—so that it forms with the lower wall of the meatus which is at this age membranous, but later becomes osseous, a very acute angle, and lies nearly at the same plane as the upper wall of the ear passage.

From this condition of the meatus, it is evident that man just after birth has no better hearing than other animals of the same age, which are born with an impervious meatus. "With regard to the sense of hearing, it is first remarked that all children for sometime after birth are completely deaf, and it was not until the middle of the fourth day that Professor Preyer obtained any evidence of hearing in his child. This child first turned his head in the direction of a sound in the eleventh week, and this movement in the sixteenth week had become as rapid and as certain as a reflex. In the twenty-first month it danced to music, and in the twenty-fourth imitated song; but it is stated on authority of other observers, that some children have been able to sing pitch correctly, and even a melody, as early as nine months. One such child used at this age to sing in its sleep, and at nineteen months could beat time correctly with its hands while singing an air."

Instillations of warm water (we would add a few grains of boracic acid or bichloride of soda to the water) into the ears of new-born children which will clear the passages earlier than they would clear themselves, as the masses of epider-

mis remain in the meatus, and they become a source of irritation.

The most painful and obstinately recurring inflammation of the external ear is produced by vegetable parasites and moist epidermal lamellæ, which generally are superposed one upon another and may produce a closure of the canal, or may form a mould-fungus sometimes of light, sometimes of darker color. This almost always belongs to the aspergillus family.

Animal parasites take up their abode in the human meatus, and act as irritants. This is to be suspected in children who have much to do with birds, rabbits, and also with dogs and cats. The bird lice (*dermanyssus avium*) are abundant in house-birds, also in hen-houses and dove-cotes. Parasites have been found in the ear of an ox, where they were probably the cause of severe otitis externa purulenta; also in rabbits, caused by the borings of the psorospermia and gregarinas.

An otitis media (or inflammation of the middle ear) runs its course quickly in children, with early perforations of the drum-membrane, and consequently evacuations of the secretions, but will probably re-occur with the next cold in the head. This diseased condition is usually associated with dentition, but the source of the disease should also be sought usually in the naso-pharyngeal mucous membrane, which is in the immediate neighborhood of and in direct connection with the ear along the Eustachian tube. A peculiarity of the meatus in young children is quite a large opening in the lower anterior wall of the osseous canal, which is produced by irregularity in the growth of the bone at this point. This defect in ossification appears first in the child between the twelfth and eighteenth month, about the size of a cherry-stone, and opens toward the edge of the bone, and is still to be seen, as a rule, in the fourth or even fifth years as a round opening, which is gradually closed. It is evident that this opening, which is covered merely by the skin of the meatus and periosteum, must be a vulnerable spot, which purulent and suppurative processes may readily break through, forming fistulous openings towards the parotid gland and the region of the lower jaw, so that the inflammation and suppuration may extend to these regions.

The treatment of otitis externa (or otalgia) is extremely simple; if the child is strong, one or two leeches on the edge of the ear passage in front of the tragus, or upon the cartilage just below it, will be of service. Frequent ear-baths with warm water will relieve the pain. (Cotton saturated with wine of opium, and the volatile

*Diseases of the Ear in Childhood, by Von Tröltsch, which appeared in 1880 in Germany. It formed a part of Gebhardt Hand-book of Diseases of Children. Translated by Dr. L. O. Green, Wm. Wood & Co., New York.

product driven by off heat, will be found valuable to relieve pain; also a solution of sulphate of atropia, a few drops warm in the ear, is prompt to relieve acute pain.) In otitis media purulenta the removal of the secretions as soon as suppuration has begun is important, and the use of zinc sulphate and plumbi acetate in solution. (This is the old method of treatment, which is now obsolete, and syringing, except for diagnosis, has given way to wiping out the ear packed with antiseptic cotton, with the application of powdered boracic acid, by which means there has been a greater number of rapid cures. The use of small ice-bags to the auditory canal, but no cold water to be permitted to enter the meatus; and we object to warm poultices, which, though they relieve the pain, etc., yet always produce a decided loosening and maceration of all the tissues, etc.)

Rupture of the membrana tympani occur when the column of air over it suffers a sudden and great condensation from a blow of the hand upon the entrance of the meatus; or in bathing, if one in diving from a certain height accidentally strikes the side of the head with the auricle forcibly upon the water; when the Eustachian tube is closed, or a collection of mucus in the tympani, the membrane is more easily torn.

If no deeper complications are present, such wounds of the drum membrane heal, as a rule, rapidly, without leaving permanent injury, as do also the punctures from needles, straws, probes, etc.; a moderate effusion of blood in the tympanum does not interfere with the healing process. The only thing necessary to be done is to abstain from irritating the edges of the wound, or from separating them. A little cotton wool should be worn on the meatus, but only laid on lightly, and not pressed hard, and the patient should be forbidden to blow the nose suddenly or violently. All instillations, syringings, or other interferences with the ear, are improper, as they will prevent healing by first intention.

Congenital malformations of various kinds have been observed in the tympanum, as absence of the cochlear or vestibula fenestre, the ossicles wanting, or separation of the same bone, or anchylosis of their joints, etc. The mastoid process does not exist in the child as a rounded prominence, but in early life is flat, and contains only a finely porous osseous tissue; pneumatic cells are found which form the mastoid process, but these do not reach their full development until puberty.

The tympanum in the fetus and new-born child. So long as the child has not breathed, the tympanum

can contain no air. Heretofore, anatomists have assumed that at the time of birth the cavity was filled with mucus, which gradually disappeared with the entrance of air during the breathing and crying of the child. This, however, is not so; but the tympanum of the fetus is filled by the mucous membrane itself, which, especially on the labyrinthine wall, is in a marked hyperplastic and swollen condition, while in the adult the mucosa covering the promontory is extremely thin—almost like a serous membrane. In the fetus it appears as a thick gelatinous tissue, reaching to the inner surface of the drum membrane, and therefore almost entirely filling the tympanic cavity. On closer examination, this mucous-membrane-cushion of the tympanum consists of embryonal connective tissue, or the mucous tissue of Virchow, viz., of a mucous fundamental substance, with a well-developed net-work of cells; its surface contains blood vessels, and is covered by a beautiful nucleated polygonal pavement-epithelium.

Wriden and *Wendt* have claimed that its disappearance is wholly dependent upon the breathing, and have proposed this as a substitute for the lung test in medico-legal investigations in regard to the extra-uterine life of a child when the head only is examined. It should be emphasized here that the labor itself, especially if it continues unusually long, may directly involve danger and injury to the middle ear of the child. *Wendt* was the first to report that sometimes materials were found in the tympana of new-born children which originated directly from the amniotic fluid or from the maternal organs (fine hairs, vernix caseosa, meconium, vaginal mucus), and he assumed that they must have reached the ear by the inspiration of the thorax during labor.

Ed. Hofmann showed later that during the birth, and produced by the separation of the placenta, very frequently respiratory movements of the chest occur, with which necessarily inspiration of the media surrounding the child must take place in the middle ear as well as the lungs; that the entrance of a large amount of foreign material into the one or the other organ may act as a pathological irritation, and under certain conditions produce a mechanical closure of a narrow cavity.

Attention must here be called to the fact that in children, the dura mater and the tympanic mucous-membrane are in much more intimate connection than is the case in later life. In establishing the degree in which the middle ear in childhood is predisposed to disturbances and

diseases, we must remember the all-important fact that both Eustachian tubes enter the naso-pharynx.

The hyperplastic and inflammatory affections of the palatine tonsils, so common in childhood, act in a similar way in closing the tubal orifice, as when they attain a larger size, they press the palate and the surrounding mucous-membrane up against the pharyngeal orifices, and like a foreign body, produce chronic stasis in the blood vessels and act as a continual irritation to all the neighboring tissues. Children living in crowded nurseries, which are also used as water-closets, and also often for cooking, drying of linen, etc., and those who frequent overcrowded and unventilated school-rooms, are subjected to a bad, and for the purpose of breathing, unserviceable air, an evil which is receiving more and more attention, at least in hygienic writings. Too much stress can not be laid upon the evil effect which too warm, too damp, or impure air, in the house and in the school, exerts upon the health of the child. The majority of the severe diseases of the nasal and pharyngeal mucous membrane, of continuous cold in the head, of angina, croup, and diphtheria, occur in childhood and during school life. As a synopsis of the points which have been brought forward, it may be asserted as a fact that in childhood, aside from a few weeks immediately following birth, an unusually strong predisposition to disease of the middle ear exists, owing on the one hand to the double influence of the peculiar morphological relations of the ear and the pharynx, and on the other hand to the diseases and conditions of life to which the child is frequently exposed.

In later times, there will be found in "Koppen's Marburger Dissertation," of the year 1857, a statement which is applicable here. He examined only new-born children—the oldest twenty-five days old—and found the tympanum empty in six, while in eighteen that cavity contained fluid, and in four of these eighteen the fluid was true pus.

Without any knowledge of these preceding statements, Von Tröltsch called attention, in 1858, to the frequency of collections of pus in the tympana of small children. In forty-seven petrous bones taken from twenty-four unselected children out of the polyclinic or lying-in hospital in the course of several years, he found the middle ear normal in only eighteen; the other twenty-nine ears showed in various degrees the appearance of a purulent, rarely of a mucous catarrh.

According to Schwartze (1864), for every five examinations of new-born children, in two the tympanum will be found filled with pus.

Wreden (1868) found in eighty ears which he received in the course of four months from St. Petersburg Foundling Hospital, a normal middle ear in only fourteen.

Edward Hofmann (1873) examined in Innsbruck twenty-four petrous bones from children varying in age from thirty-two hours to four weeks, and found the tympanum filled with pus in seven cases, while in the other seventeen it was perfectly or nearly normal.

The greatest number of investigations have been made by Kutzcharianz (1875 and 1872) from children out of the Moscow Foundling House, the ages of which varied between a few days and seven months. From about two hundred and thirty accurately described cases, the tympanic mucous membrane was normal in only thirty; in fifty, it showed either a slight or intense catarrhal inflammation; and in one hundred and fifty the tympana were filled with yellow-green pus, with occasional clumps of mucus mixed with blood. In four of these cases of purulent inflammation, the pus was of an ichorous character.

We may assume that Zanzal is right in considering that the pus which is found in the tympanum a few days after birth is chiefly not an inflammatory but a degenerative product of the embryonic tissue retained in the cavity owing to some impediment in the tube.

As would be expected, the numerical proportions between normal and pathological tympana varies very much in the different reports; of the ears examined by V. Tröltsch, in Würzburg, 38 per cent. were normal; of those by Wreden, in St. Petersburg, 17½ per cent.; by Hofmann, in Innsbruck, 70 per cent.; and by Kutzcharianz, in Moscow, only a little over 13 per cent. showed tympana without hyperæmia of the mucous membrane.

(To be continued.)

CORRESPONDENCE.

A Rumor Contradicted.

EDS. MED. AND SURG. REPORTER:—

We are astounded to see in the MED. AND SURG. REPORTER of January 27, that you received a telegram stating that in one family in the city of Dallas, Texas, there were "Nine persons who were poisoned by eating pork, supposed to be trichinous. Three of them died." Well, Messrs. Editors, we heard nothing of a single case. Besides, we have made inquiry of the undertakers, and they report that not a single case have they ever heard of in this city. We are happy to say that we have a people here who eat cooked meats;

besides, they live mostly on beef, mutton, etc., and little pork.

Therefore we ask the name of the gentleman who sent this dispatch to your city.

Respectfully,

J. M. PACE, M. D.
G. BEAUMON, M. D.
H. A. MOSELEY, M. D.

Dallas, Texas, February 10.

[The dispatch was extracted from the daily papers of this city. We do not know its author.]

—EDS. REPORTER.

NEWS AND MISCELLANY.

New York Ophthalmological Society.

At the annual meeting, held January 8, 1883, the following officers were elected:

President.—George R. Cutter, M. D.

Vice-President.—David Webster, M. D.

Secretary and Treasurer.—Jas. L. Minor, M. D.

An Epidemic of Syphilis.

An epidemic of syphilis has recently occurred in Sheffield, England, through the agency of a syphilitic midwife, who attended a number of cases of delivery in married women, all of whom contracted the disease. The woman has been committed for trial, charged with having "wilfully and maliciously caused grievous bodily harm" to the complainants.

Our School for Post-Graduates.

The *Lancet*, January 20, 1883, says: "Philadelphia is about to follow the example of New York in establishing a school for post-graduates." We would inform our transatlantic contemporary that Philadelphia was the first city in the United States to establish a school for post-graduates, which was done in connection with the University of Pennsylvania, and has been now in successful existence for nearly two years.

Office Lights.

Few matters are more important to the furniture of an office than a good light. For this purpose, we can speak with special favor of the "Perfection Student Lamps," devised by Mr. R. G. Hutchinson, 44 Maiden Lane, New York City. They have all the appliances to secure entire safety, are handsome, strong, and the cheapest for the money which we have anywhere seen. Any of our readers who want a really good lamp, will do well to send to Mr. Hutchinson for one of his descriptive circulars, with particulars.

University of Pennsylvania.

At the monthly meeting of the Trustees of the University of Pennsylvania, February 6, a gift of \$5,000 for the endowment of a bed in the University Hospital was received from Henry Ingersoll. A petition was received requesting that the doors of the University be opened to women on the same terms as to men. The petition was referred. Frederick A. Genth, Jr., was elected Assistant

Professor of Chemistry, and Albert S. Bolles was chosen Professor of Mercantile Law and Practice in the Wharton School of Finance and Economy.

Officers of the New York Academy of Medicine for 1883.

President.—Fordyce Barker, M. D., LL. D.

Vice-President.—H. P. Farnham, M. D.

Recording Secretary.—W. H. Katzenbach, M. D.

Corresponding Secretary.—J. G. Adams, M. D.

Treasurer.—William F. Cushman, M. D.

Trustee.—Gouverneur M. Smith, M. D.

Treasurer of Board of Trustees.—Charles Wright, M. D.

Member of Committee on Admissions.—E. L. Partridge, M. D.

Member of Committee on Ethics.—H. E. Crampton, M. D.

Member of Committee on Education.—J. C. Dalton, M. D.

Member of Committee on Library.—A. McLane Hamilton, M. D.

Contaminations in Drinking Water.

At a recent meeting of the Academy of Natural Sciences in this city, while discussing the subject of the pollution of the Schuylkill water, Mr. Edward Potts reminded the members that a recent similar condition of the Boston water had been ascribed to the decay of fresh water sponges in the water-pipes. He had recently examined several portions of our water works with a view of ascertaining how far decaying sponge growth might be considered the cause of the offensive condition of affairs with us. Near the crest of the dam, in the forebay and in the reservoir, sponges had been found growing more or less abundantly, but nowhere in such quantities as on the lattice work protecting one of the discharge pipes in the reservoir. Here the *Mayenia Leidyi* almost interfere with the flow of the water. This species is a dense sponge with small, closely-packed spicules, and a comparatively small amount of sponge flesh or sarcodæ. Indeed, so scanty is the amount of matter which could become offensive by decay, that a very large amount of sponge would be required to contaminate a small quantity of water. Various species of rotifers and protozoa were also found in the reservoir and elsewhere; especially an abundance of *spongilla fragilis* in the canal between the two locks opposite Fairmount. The result of his investigations had been the conviction that the offensive character of the river water could not reasonably be assigned to decaying organisms.

The President, Dr. Leidy, declared that instead of decaying animal matter being the cause of the pollution, he was convinced that the actual cause, whatever it might be, was rapidly destroying the life of various sorts which formerly flourished in the river. Some years ago such organisms as *urnatella*, *paludicella*, and *plumatella* had existed abundantly in places which had been found recently to be reeking with filth. The Schuylkill mud is saturated with oil, and only the remains of mollusks and aquatic insects can now be found in it. It could not be doubted that the impurity of our river water was due to the drainage from mills, factories, and surrounding habitations.

Personals.

—The appointment of Dr. Robert H. Allison, as Port Physician of Philadelphia, will meet with universal approval. Dr. Allison stands high in the profession, and is a gentleman of wide general culture as well. No selection by the Governor could have been more appropriate.

—Doctors Reed and Wiley, of the Dixmont Intane Asylum, have sued the *Erie Herald* for defamation of character, laying damages at \$40,000. The suit grows out of articles published by the *Herald* reflecting on the management of that institution, based on statements of Dr. Sevin, an ex-inmate of the asylum. Them anagement deny the charges, and claim that the doctor is still deranged.

—At a recent meeting of the Camden Microscopical Society, Dr. A. P. Brown called the attention of the members to the important fact that nearly all kinds of bitter drugs, such as nuxvomica, chamomile, etc., have lately greatly advanced in price, owing to the large purchases made by brewers, who use them in the manufacture of beer in the place of hops, of which the crop this year was a failure.

—An extraordinary security was offered by a man who recently advertised in a Berlin newspaper for a loan. The advertisement ran as follows:—"A medical student whose means are exhausted would like to meet with some one who would advance him the necessary sum to complete his studies, at a moderate rate of interest. If necessary he would as a guarantee at once marry his creditor's daughter, or, if he prefers it, would give an undertaking to do so on passing his final examination."

—The late eminent artist and poet, D. G. Rossetti, instead of seeking health and consolation in travel, in company and in exercise after his wife's death, shut himself up alone amid mediæval relics in a large, gloomy house. He sought relief from grief and sleeplessness in chloral, and, as the London *Daily News* declares, this drug at last distorted his ideas and his sentiments even about his friends. Some magazine criticisms, which a healthy man would have fumed at and forgotten, led him to the belief that he was the victim of a of a conspiracy. His bodily health could not support the stress of his intellect, and the result was, in a literary sense, disastrous.

Items.

—The juice of the cow-tree of South America has been analyzed by a French chemist, who finds that it really possesses many of the constituents of cow's milk.

—A Philadelphian last week drank a pint of whiskey at a draught. In a few minutes he fell to the floor insensible. A physician was called, and after eight hours work, the man was restored to consciousness. Query: Was it worth the trouble?

—The latest information from Southwestern Virginia reports the ravages of small-pox as extremely alarming. Neither the people nor the physicians in that section have any adequate

knowledge of the disease to enable them to deal with it successfully. They are consequently terror-stricken by its appearance, and refuse to venture near any houses in which there is a small-pox patient.

—By a law which has just come into operation in Italy, the sale of patent medicines throughout the kingdom is prohibited unless the precise composition of the medicine is stated. The promulgation of this important decree has been made by the Minister of the Interior, the Customs, and the sanitary authorities. One well-known chemist in Rome has at the present moment nearly \$500 worth of patent medicines lying at the Dogana, and likely to have to remain there or to be sent back to England undelivered. For the future, travellers will have to smuggle their favorite drugs into Italy.

 QUERIES AND REPLIES.

MESSRS EDITORS.—What is the best hand-book for physicians who wish to make a correct diagnosis, and enable them to order suitable glasses in cases of astigmatism, myopia, hyperopia, and various other diseases of the eyes.

Pa.

N. S. B.

The best work of the kind we are acquainted with, is Landolt's *Manual of Examination of the Eyes*. Price, \$2.60.

MED. AND SURG. REPORTER.—I would like to inquire through your columns if anesthetics in labor have the tendency to prevent the secretion of milk. Have administered the A. C. E. mixture repeatedly, during the past four years, both in instrumental and natural labors. In a *very few* cases the mammary glands refused duty after two or three weeks. My experience without the anesthetic is much the same.

M.

MESSRS EDITORS.—May a physician *bid* for the medical and surgical treatment of the poor, in response to an advertisement of the Board of Supervisors of the county, the same as mechanics bid for building contracts, without violation of medical ethics?

C., of Ill.

Ans.—It is often done, but we think that the result is a lowering one to the profession and injurious to the public.

Dr. S. K., of Va., asks for reports of diseases in women distinctly traceable to the avoidance of conception, and further with reference to the manner of avoidance.

Dr. Alonzo, of N. Y.—We are always glad to receive and publish short, practical articles from the daily observation of physicians. Send your MSS. at any time.

Dr. C. C. Vanderbeck, lecturer on hygiene and sanitary science, in Wagner's Institute, Philadelphia, will be grateful if his professional brothers, throughout the country generally, will send him any monogram or reprint in the department of sanitary science. His address is 2246 Ridge Av., Philadelphia.

 DEATHS.

FISHER.—On the 12th inst., after a brief illness, at Cologne, Germany, Alexander M. Fisher, M. D., in the 26th year of his age, son of the late Edward M. Fisher, and grandson of the late Colonel Alexander Ming.

RAND.—In this city, on February 14, 1883, B. Howard Rand, M. D., in the fifty-seventh year of his age.

RANNEY.—In New York city, on Thursday, February 15, Lafayette Ranney, M. D., in the 64th year of his age.

STAUFER'S
HARD RUBBER UTERINE EXAMINING INSTRUMENTS.

SERIES OF SPECULUMS ENCASED.

Prices—The series of four speculums and conduc-tors, encased, \$12.00. Weight, about 12 oz., made so com-pact as to carry in an inside coat pocket. Single with con-ductor, \$2.50. Taken back at cost when a case is desired.

This screw top hard rubber case contains four graduated, hard rubber speculums. Den-tal red enamelled inside. By trial it was found that this color attracts the light to greater advantage than any other, and the admission of a converging column by their

being slightly taper; together with the admission of a size by the conductor that takes in the entire cervix, and thus reveals it as plainly as if located externally. This clear view is seen by holding the hand against the bevel, while the funnel points towards a window even at a distance.

Position—The dorsal (fully explained in full catalogue) admits the shading of the lower part of a window and draws the light from the upper; when slight from opposite is to be excluded. The slight taper of three-eighths inch from mouth to (c) displays room to work within, and admits a second person to see as plainly as the operator. The rounded con-ductor enters easily, and the speculum with its slight taper moves freely after.

Obviating Exposure—A thin sheet thrown over the patient and the edge surrounding the funnel end of the speculum, completely prevents exposure, and yet does not interfere with the rotation of the speculum, nor its mani-pulation. Full direction and exchange privilege accom-panies each purchase of a speculum.

Any of this series of instruments delivered free by the Medical and Surgical Reporter Office, on receipt of quotation prices. The Catalogue, illustrating and describing over 150 in size and style uterine examining and supporting instruments, also obtained through this Office.

HARD RUBBER UTERINE EXAMINING CASE.

Prices—Full case, \$8.00; Quill Canstic Holder H, or Camel's Hair Brush Holder and case I, each \$1.00. Any two of the first seven, with centre piece K, \$2.50

This case contains 10 articulating instruments, all of hard rubber except the screw joints at each end of K, and M, on caustic holder H. Also flexible sound B, is of metal. The series and hard rubber case weighs but four ounces. Lengths of parts when screwed together is 11 to 12 inches.

A, is a thin, cervix probe without bulb end, as rubber is not cutting like metal.

C, a strong sound also without bulb end to straighten up a retroverted uterus.

D, a fenestrated mover of cervix, and scraper of ro-py mucus when suspended from the os. As a mover or shifter, it is required in almost every case, and when used as a mucus scraper swab E, should be screwed on the opposite end of K.

F, and G, are used to straighten up the anteverted and retroverted uterus before introducing the speculum.

ORIGINAL DEPARTMENT.

COMMUNICATIONS.

CONCERNING SPIROMETRY.

BY A. H. HOY, M. D.,
Of Racine, Wisconsin.

In the October 7th, 1882, number of your journal, I asked of your readers information concerning spirometry, making six questions which I desired answered. Three communications have been received concerning the matter.

1. A reply from a well-known professor of diseases of the chest, who says he has no faith in spirometry, and considers the sources of error too numerous to be overcome. On receipt of this, I took occasion to address a note to the gentleman, asking for more definite information, and received a reply saying he had really never used the instrument (a water spirometer) but a few times, and had given the matter no especial study or attention.

2. The following letter from Dr. Lewis Sherman, of Milwaukee, Wisconsin:

"I have used the spirometer more or less regularly for the last twelve years. Several thousand observations have been made. I have used an instrument of my own construction. The apparatus consists of a water meter, corrected to the temperature, according to the condensation of moist air at 99° F. to 95° F. The readings of the ordinary water meters and rubber bags vary for the same lung capacity as the temperature of the atmosphere.

"Moist air condenses more than dry air, with the same degree of reduction of temperature. There are two forms of my instrument, one with

an elastic scale and thermometer, and the other with a fixed scale and thermometer, with a table for reduction of the reading as in the alcoometers.

"The sources of error are, the imperfect construction of the instrument, and inexperience in the muscular control of the respiration.

"According to my observation, the available capacity may be increased from ten to twenty per cent. by the habitual exercise of forcible inspiration and expiration, such as is required in using the spirometer.

"The spirometer is the best known instrument, or means, for measuring lung capacity. Successive observations on the same patient show quite accurately the progress of the disease in the lungs. These successive observations gave much more reliable results than isolated observations."

The third communication is from Dr. William W. Rodman, of New Haven, Connecticut, as follows:

"I have used a spirometer for several years, first Lewis' and later Marsh's rubber instrument. The cases would number hundreds, and the separate trials, thousands.

"Marsh's instruments break very readily. Two of the bags burst in my office yesterday. They require considerable practice, or mistakes will occur. Properly used, I think them useful, but I want a better spirometer than any I know of. A feeble patient has to be taught carefully how to use the instrument.

"It is often at first utterly impossible to direct the nervous energy with this novel respiratory effort. No final judgment can be reached in many cases until the first difficulties are overcome by repeated trials carried through several days.

The patient must be watched, taught, encouraged and cautioned. Definite results can be reached finally, and the vital capacity of the individual determined.

"I have found a few persons, men and women, who, at the first trial, would show a measurement far beyond the normal limit.

"As a general rule, a limit is reached after a few weeks, beyond which it is difficult to advance. I have found, however, where this limit had apparently been reached after faithful trials, that some new stimulus would give a further advance. Such a stimulus I have found in the massage manipulations, and also in static electricity. The galvanic current, in my hands, has failed to educe any such results, though I have repeatedly tried it both in mild and in heavy currents. I do not think that the Faradic current will serve this purpose, though my experiments with it are limited.

"The most striking results in my hands have occurred by the use of the spirometer immediately after stimulation with static electricity. I have been accustomed to use Hutchinson's table of vital capacity, and know of no other.

"With the proper caution and limitation, I think spirometry very valuable for diagnosis and prognosis. I am accustomed to aid my conclusions in various ways; for example, by measurements with the tape, and with callipers. Within moderate limits, I think that the conclusions to be drawn from the use of the spirometer can be relied on, and I have known mistakes made by famous auscultators. In the use of this instrument, the patient is encouraged to make efforts which are likely to be of great service, unless they are too violent at first, or are made in a cold room.

"As long as progress is made, the courage is kept up, and in cases where the indications are unfavorable, the instrument itself tells the story, and the physician is not obliged to put an unfavorable prognosis into words."

I desire to reply to these letters through the *MED. AND SURG. REPORTER*, and thus make public the results of my experience in spirometry, and to describe the means used, which are so simple as to be within the reach of any one, and I hope some interest may be awakened in the subject. In fact I know of no study in which physicians will find so much to interest and instruct them, as in spirometry; more especially as it would seem to be a new field for work, judging from the paucity of replies I received to my inquiries; and better instruments are to be invented, and more correct tables devised to work with.

I use the rubber bag spirometer, known as Marsh's, with certain modifications and additions. Finding that the bags furnished with the instrument were easily broken, and varied too much in thickness, I procured a supply of rubber gas balloons, such as are sold to children as a toy, at fairs and circuses. These can be had of F. Paturel & Co., New York city, at a cost of about three dollars and fifty cents per gross.

These answer the purpose admirably, and leave nothing to be desired in this respect. I use also a beef's bladder, which is prepared for the purpose by divesting it of the outer and coarser muscular coats, and then turning it inside out; this can readily be done when the bladder is well macerated in water. Next mount it on a rubber tube (similar to that used in the spirometer) and inflate the bladder to its fullest capacity, and allow it to dry thoroughly. After this is accomplished, by repeated rubbing, and folding it in the hands, it will become as white and soft as a kid glove. The next essential is a pair of steel callipers, with a scale of quarter inches, suitable for measuring the width of the shoulders from acromion to acromion.

Before using the spirometer, it is very necessary to be sure that the tape scale shall read accurately. To insure this, I have a fixed scale by which I set the tape, and by which I prove my spirometer from time to time. This consists of a piece of wood three feet long and three inches wide, scaled in its length into inches and fractions of an inch. At one end an upright piece one foot high is fastened, exactly at a right angle. A carpenter's square is held on the long piece of wood so that the short arm is parallel with the upright; the rubber bag is now inflated, while it remains between these two, until it barely impinges on each, and the diameter of the inflated globe is at once known from the scale on the long arm of the frame. The diameter of a sphere being known, a simple calculation gives the cubical contents. The tape scale is now fastened to the bag so as to read the correct amount. I generally prove the scale to three diameters, viz., six, seven, and eight inches, the capacity of these being one hundred and thirteen, one hundred and seventy-eight, and two hundred and sixty-eight cubic inches. The bladder is used, often expelling all air from it by simply folding it in the hand, to receive the air from the lungs of such persons as have not the muscular power to inflate the rubber bag. The air once received into the bladder is transferred to the rubber bag by connecting the mouth-pieces, and measured as ordinarily done.

It is well to use the rubber bag and the bladder in any cases that are in any way doubtful or uncertain. From four to six observations should be made, half with the person standing and half in the sitting position, and the average of these should be taken as the vital capacity.

The calipers are used to determine what I take the liberty of terming the "vital number" of the person. It is ascertained by taking the calibre of the shoulders from acromion to acromion, adding to this one-half an inch, and half of this sum will constitute the "vital number."

This is not, as it may seem, an empirical formula. It is a sort of "lightning-calculator" mode of reaching certain dimensions of the chest that I formerly made several measurements and calculations to attain. Concerning the fixed ratio which the different measurements of the chest bear to each other, I would refer to page 37 of "Hammond on Hygiene." The vital number having been ascertained, the vital capacity is found by reference to the following table, which I have prepared and tested by repeated observations. Hutchinson's scale of vital capacity, based on the height of the person, failed too often to give satisfaction; and this is not to be wondered at when we remember that his observations and deductions were made in British soldiers, men who may be supposed to be somewhere near anatomically correct and robust as to health—such, in short, as are never seen in a doctor's office. The table I have devised is based on a ratio between size of chest and vital capacity. I give the numbers from six to nine, increasing a quarter of an inch each, which I regard as accurate enough for all purposes.

Vital Number.	Vital Capacity.	
	MALE.	FEMALE.
6.	108.	82
6.25	122.	90
6.50	137.	102
6.75	153.	112
7.	170.	124
7.25	190.	136
7.50	200.	150
7.75	230.	164
8.	240.	180
8.25	250.	186
8.50	260.	194
8.75	290.	214
9.	330.	240

I claim that a person possessing the vital capacity which their vital number calls for according to this table, may safely be set down as having normal and healthy lungs. If they do not reach the standard it may be on account of mus-

cular weakness of the respiratory apparatus, or it may be a filling up of the air-cells, or loss of lung tissue. The cause and nature of the failure to reach the normal vital capacity is for the physician to determine from other data to a beginner in spirometry, the following points will be of aid:

1. A person may be in his usual or comfortable health and still be using, or have the use of, only a part of his lung tissue, and yet have no disturbing chest symptoms.

2. Persons past middle life, or who are aged, may have a carbonaceous deposit in their lungs, which does not constitute a disease. The osseous frame-work of the chest of this class of cases loses its flexibility also, and due allowance must be made for this.

3. Those who have long used their lungs violently will show a vital capacity far beyond this table. The fact is, their lungs hold more than the normal amount of air. They are stretched, not to say developed. It does not, by any means, follow that their lungs are the better for it.

4. Learn spirometry first by measuring the lungs of as many vigorous, healthy subjects as possible; next examine those whose lungs have been, or are now diseased, cases whose history you are familiar with, and who are not now under treatment for lung troubles, but who are in their usual health. Pass from these to those in all stages of diseased lungs, and I am sure you will establish some points you can rely on with confidence, and will be able to make a diagnosis and prognosis in very many cases, which, with auscultation and percussion, would have embarrassed you seriously. If startling inconsistencies or contradictions occur, make every effort to clear them up, or devise some new plan by which their repetition can be avoided.

I should be pleased to hear from any one interested in spirometry, who may wish further information.

A PECULIAR TYPE OF FEVER.

BY DR. J. M. PINKSTON,
Of Alabama.

As it may be of interest to the readers of the REPORTER, I ask permission to give notice through its columns of a very peculiar type of fever that prevailed in this country during the year 1882, commencing about the 1st of July, and subsiding about the 1st of December, which affection leads me to believe there are, perhaps, some epidemics of mistaken typhoid fever, as it is pronounced by some physicians to be typhoid. There seems

to be a variety of opinions as regards diagnosis, some regarding it as a congestive form of remittent fever; others typho-malarial, typhoid, etc. I will proceed to give the symptoms and peculiarities as correctly as my experience in such cases will allow me:

The patients usually have the premonitory symptoms of typhoid fever, with, in most instances, a slight pain in the stomach a day or two before access of fever. The fever is usually ushered in with a chill, followed by headache, nausea, and vomiting; in some cases, cold feet and hands, and tenderness and continuance of pain, in most cases, over region of the stomach, and almost invariably tenderness at a point midway between the hips, but no iliac tenderness. The tongue is usually a little red around the edges, and lightly furred in the commencement of the fever, and very heavily coated and very red, as in typhoid fever, a few days afterwards. The bowels and stomach are generally uniformly tympanitic, though sometimes only a portion of the bowels, and occasionally in the commencement, the bowels are free from tympany altogether; but the stomach is most invariably so, from beginning to end. The bowels are usually constipated; in some cases so much so it requires an enema from time to time to move them. I should have stated that the fever in the commencement is high, in children sometimes attended with convulsions. Two of my patients were seized with convulsions, the first symptom noticed, though no doubt the usual prodromic symptoms existed unnoticed. The symptoms in the commencement, in some cases, indicate violent congestion of the stomach and bowels, and, as indicated by breathing, congestion of lungs, but there are no physical signs thereof. Some cases also have a slight sore throat, enlargement of tonsils, and a little irritation of bronchial tubes, and consequently a little cough.

The above symptoms are all that are observed in a typical case of this fever, except as to the movements from the bowels, which are always mixed more or less with mucus, and sometimes the larger portion consists of much.

Now a few words as to treatment, which, medically speaking, presents nothing peculiar, if viewed from a natural pathological standpoint, as suggested by the symptoms, and not as typhoid fever. The first object in treatment is to relieve the engorged state of stomach and bowels, with the most soothing medicine possible. I prefer calomel for the purpose, which I usually give in divided doses until I get several free movements from the bowels. In the meantime I direct a hot

mustard foot-bath, and cover the stomach and bowels with a large mustard plaster, and not a poultice, which I continue to use daily, until the patient is decidedly convalescent. After thorough evacuation of bowels, give quinine in decided doses, not less than forty or fifty grains to an adult daily. I usually commence at midnight, regardless of fever or circumstances. If the patient is seen late in the evening, it may be necessary to combine calomel and quinine together. I almost invariably give good whiskey or brandy from the beginning—a teaspoon to a tablespoonful with each dose of quinine; which, owing to the great amount of torpor of stomach and bowels and general prostration, I regard as a very important auxiliary indeed. After the first twenty-four hours, give turpentine in moderate doses, for a few days.

The above comprises the treatment, with the exception of a few details, such as the use of opiates, diaphoretics, etc., as may be indicated.

A word as to hygiene, which is a very important desideratum in the management of this affection. The diet should be absolutely in a liquid form, and the most nourishing and concentrated. It should be taken in small quantities, at short intervals, and continued in like manner for a few days after cessation of fever, during which time the patient should remain absolutely quiet in bed.

As to the peculiarities of the fever in question, if improperly treated or not treated at all, and in some cases in spite of treatment, it will last from two to six weeks; but if taken in time with all the symptoms well developed, and properly treated, will yield, in my experience, almost invariably, within thirty-six to seventy-two hours; if due precaution, as to diet and exercise, is not taken, the patients will have a relapse from time to time until the affection seems to become a fixed condition, and will not yield under any manner or form of treatment—cases exactly identical with others that subside within thirty-six or forty-eight hours. I have observed some cases of intermittent fever of the quotidian type that were followed by a greater amount of prostration after a few paroxysms than ordinary remittent fever of a week's duration; these cases presented the usual symptoms of the cases under discussion, red and furred tongue, tympany of stomach and bowels, tenderness and pain in the epigastric region, etc.; in fact it seems to have been a modified form of the same affection. I have seen a few cases of diarrhoea followed by dysentery, attended by the general symptoms of the above affection, red tongue, tympany of stomach and bowels, etc., without the

fever. I have also seen a good many cases of sore eyes, attended with severe neuralgic pains, red tongue and enlargement of papillary glands on the end of tongue, which was always the case in this affection, that were not benefited by the usual treatment, but yielded readily to a cathartic followed by the systematic use of quinine for several days. Whether the sore eyes were due to the same cause as the fever, I am not prepared to say, though I have not seen any one with sore eyes or dysentery, that afterwards had this peculiar type of fever. Now the mere idea of a large proportion, five-sixths or perhaps nine-tenths of my cases, having yielded to treatment in a few days, excludes the possibility of it being typhoid fever, or "typho-malarial," which latter, in my experience, will not yield in less than ten days, under any treatment that may be instituted; and the fact of it yielding in so short a time has given rise to the opinion of some that there is no such combination. As to the diagnosis, I regard the fever as dependent on a circumscribed inflammation of the bowels, and, in the absence of a name for the affection, I have pronounced it catarrhal inflammation accompanied by a general engorgement of the entire mucous surface; the powers of digestion are almost entirely perverted, there being a total inability to digest solid food of any description, and milk or other liquid food, except in very small quantities; I could predict a relapse with almost as much certainty, after giving a glass of milk, as if solid food had been given; they were generally unable to digest as much as half a glass of milk at one time.

It is reasonable to suppose that when the stomach is so very deficient in powers of digestion, its powers of absorption are also deficient; for this reason, as well as because of the great amount of prostration from the beginning, I give a little whiskey with each dose of quinine, which answers a double purpose, as a stimulant and promoter of absorption. As to diagnosis, I should like to have the opinion of older members of the profession.

THE RECUMBENT POSITION IN TYPHOID FEVER.

BY DR. GEO. HAMILTON,
of Philadelphia.

In the *REPORTER* for February 3 may be found "Observations on the Management of Enteric Fever," read before the College of Physicians by Dr. James E. Wilson. After the reading of the paper, Dr. Hamilton is quoted as "speaking of the great importance of preventing hypostatic conges-

tion by changing the position of the patient from time to time." These are the words, however, of Dr. Wilson, and were expressed by him after Dr. H. had said: "In view of the frequent occurrence of hypostatic congestion in the latter stages of typhoid fever, and its great danger, would not the plan recommended of placing the patient in bed from the first moment of attack, and keeping him there, in the recumbent position until the termination of the disease, not suffering him to arise even to obey the calls of nature, be well calculated to increase the liability to the dangerous condition alluded to?" That there is danger in this exceptionally novel, tentative mode of treatment, is tacitly admitted in the advice to change the position of the patient frequently. But how can this effectively be done, since the patient is to be kept, without intermission, in the recumbent position, so that whether upon his back, or on the right or left side, he is yet recumbent? Again, a very large number of typhoid cases now seen are slight, so that during the first two weeks the patients are able to move about, change their position in bed, get out and into bed with comparative ease when nature calls, and would much prefer so to do than submit to a regimen so irksome and inconvenient as that proposed. But this is not all. Many persons, females especially, are shocked at the idea of remaining in bed while urinating, or the bowels are being moved, and the fact that cleanliness in this way can scarcely be secured presents another objection. Nor is this all, for many persons are well nigh incapable of freely urinating, or evacuating the contents of the bowels, whilst in the recumbent posture, and the efforts of a patient to do so are not only annoying, but exhausting.

Let it be borne in mind that these objections have reference only to the earlier periods of the disease, and to patients who are quite able to assist themselves; for in the latter part of typhoid fever, when the stools are apt to be frequent and loose, and the patient exhausted, the bed-pan and the urinal, or something equivalent, are indispensable. A few years before the death of Dr. Wm. Gerhart, he informed the writer that fewer deaths, in proportion to the number of cases, had latterly occurred in this city than in the earlier years of his practice. He knew of no cause for this, but had known the same thing to occur many years before in Paris, where he had assiduously applied himself to the investigation of typhoid fever, and thus laid the foundation of his future eminence as an authority upon this subject. The rate of mortality in the hospitals of

Paris, he said, had varied in consecutive years from one death in three to only one death in seventeen to twenty cases, and this too under the same physicians, similarity of treatment and conditions. If the ratio of mortality in typhoid fever cases in this city is not greater now than at the time alluded to, it is evident that many of them are of a character that does not demand, in the early stage, the recumbency and quietude enjoined, and that the spontaneous tendency of a large majority of these cases is to recovery. A constant and long-maintained recumbent position, and the inaction that attends it, are not, as a rule, beneficial to the sick or to those in good health, as may be seen in the backache and headache so often complained of after a few days of confinement to bed. In typhoid fever there is often a disposition to congestion at an early period of the disease, and every effort should be made to prevent this unfavorable condition. But can this be done by the plan proposed? Physical inaction begets vital, molecular inaction; and that is the prelude too often to passive congestion, and this means diminished vital power, the result of the imperfectly oxygenated blood that attends such congestion. Whenever venous congestion takes place, the brain, spinal marrow, and, consecutively, the whole nervous system, deprived of the stimulus of well oxygenated blood, languishes, and hypostatic congestion, not of the lungs only, but of every other organ of the economy, ensues to a degree that renders doubtful the recovery of the patient.

This is, in fact, the great source of danger in typhoid fever, and probably occasions the death of more patients than supervening inflammation, acute or sub-acute, of the brain respiratory or abdominal organs, or perforation, combined. A large majority of the deaths occur in the third or fourth week, and it is at this period of extreme exhaustion, when low muttering delirium, stupor, visual illusion, picking at the bed clothes, twitching of the tendons, and other analagous symptoms occur, that the propriety of the term typhoid is made manifest, as well as the extreme danger of the patient. During a practice of more than half a century, four cases have come under notice in which the patients were not confined to bed, but regularly dressed themselves every morning, at times going out to walk or to attend to some business or other matter, and again throwing themselves upon a bed or couch for rest. Of these one of singular interest may perhaps here be alluded to. A wealthy farmer, residing on a beautiful site on the Brandywine, a few miles below the

battlefield, his wife, and a domestic, were attacked with typhoid fever. A married son occupied a house about two squares distant, and was in the habit of making daily visits to his parents, who, as well as the domestic, were well advanced in convalescence when the son was attacked with the disease. He was at no time confined to bed, but would occasionally rest upon a couch. In about three weeks from the attack he sent for me—the first visit of a physician: perforation had taken place, and in 35 hours he was a corpse. Cases, then, such as these may have occurred oftener than supposed, especially when no intercourse with another typhoid patient could account for the attack.

The prominent, peculiar feature in the paper of Dr. Wilson is found in the rigid and constant confinement of the patient to the recumbent position, from the moment of attack until its termination. This proposition brought to mind a lecture before the Philadelphia County Medical Society last season by Dr. Wm. Pepper, in which the same treatment was earnestly advised, a rather restricted diet enjoined, and a medication, as the writer thought, conservative and beneficial. Yet the almost unheard-of success, 98 per cent. of recoveries, is, under any aspect, of difficult explanation. If, however, after further and repeated trials of this treatment, a similar success is obtained, may we not all, with one accord, exclaim, "*Laus Deo!*" that the dread-inspiring typhoid is at length shorn of its terrors.

TYPHOID AND MALARIAL FEVER.

BY W. A. EDWARDS, M. D.,

Asst. to Prof. Clin. Med., Univ. of Penn.

By recording cases from one's practice, a mass of observed facts are at last accumulated which enable the profession to intelligently study and treat disease from experience and actual cases, rather than by theoretical niceties.

Compilations are of little value, and if the profession would devote their time (which many are giving to collecting other men's views) to simply putting on record their own observations, no matter how insignificant or unimportant a single case or example may seem to be, the aggregate would be a vast fund of knowledge which we may consult at any time with advantage. Above all, we should carefully study all cases that are not according to an admitted type, studying all exceptions to rules, never thinking of them as unmeaning or accidental.

As Sir James Paget says: "Not one of them is

without a meaning; not one but might be the beginning of excellent knowledge, if only we could answer the question, Why is this rare? or being rare, why did it, in this instance, happen?" The same eminent authority further says: "Good specimens, typical specimens (of disease), must be at hand for the teaching of pupils who have to study illustrations of the accepted descriptions of disease; but it is among bad specimens (non-typical) even as it may be among exceptional cases, that those who are past pupilage, though they may not cease to be students, may study the variations of disease."

I therefore present the following case as being somewhat out of the common:

On November the 28th, 1882, I was called to attend John C—, æt. 26. Upon examination, the patient was found to have a temperature of 104°, tongue heavily coated, hepatic tenderness, little, if any, enlargement of the spleen, bowels constipated. The abdomen presented a few non-typical spots. I was informed that the man was taken sick on the 22d, confined to bed, and on that date had a chill of moderate severity, followed by a fever and a sweat; this was repeated twice a day, at 2 p. m. and 3 a. m., for six days, the entire paroxysm, viz., chill, fever and sweat, lasting about three hours.

From the history, locality in which he had lived, signs, etc., it was diagnosed that our patient was suffering from a double quotidian intermittent.

Quinine was administered, as in those cases, followed by five grains hydrarg. chlor. mit. and a saline. The temperature was affected but little by the quinine, and the calomel produced a very exaggerated action. This put us on our guard, and the fact that we were unable to catch on a febrile period, although the temperature was taken six times in twenty-four hours, made us waver in the diagnosis, which was utterly routed, when, on the morning of the 30th, the eighth day of the disease, typical typhoid fever eruption appeared on the abdomen.

The patient now passed through an ordinary attack of typhoid fever, with a typical temperature sheet, marked, however, by great diuresis of the pulse, with impending heart failure, which was successfully combated by cardiac and general stimulants.

On the 30th of December he was up and about, though greatly weakened. Three days later he had a chill, after which the temperature rose to 104°, followed by a sweat; this was repeated at 2 p. m. and 3 a. m., as when we first saw him,

previous to the development of typhoid fever. The patient had his double quotidian intermittent for several days, until at last subdued by quinine.

It appears that the typhoid germs, poisoning, bacillus, what you will, was able to hold the malarial element entirely in abeyance until its course was run, when the malarial poisoning again asserted its mastery.

Once more we ask the question of Sir James Paget, Why is this rare? or, being rare, why did it in this instance happen?

There is not a day that most of us do not inhale or come in contact with the germs of some frequent or contagious disease, but they do not germinate in us any more than the seeds of tropical flowers in our streets or in fields to which the wind scatters them; we do not offer the fitting soil. When the germs do germinate, the product differs according to the environment. As above seen, our patient offered fitting soil for the germination of two distinct poisons.

HOSPITAL REPORTS.

CANCER OF THE CERVIX UTERI.—COMPLETE PROLAPSE OF THE WOMB, WITH HYPERTROPHIC ELONGATION OF THE SUPRA-VAGINAL PORTION OF THE CERVIX.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA, OCTOBER 4, 1882.

BY WILLIAM GOODELL, M. D.,

Professor of Clinical Gynecology in the University of Pennsylvania.

Reported by WM. H. MORRISON, M. D.

GENTLEMEN: The first case that I shall bring before you is a woman, 37 years of age. She has had a number of children. The history is that some time ago the menses began to be a little more frequent, and that between the periods, coition caused a little bleeding.

What does that mean? It means that the male organ impinges on something which is vascular; but in order that this body may be impinged upon, it must be outside of the womb. It might be a polypus; but a polypus usually causes a dribbling of blood between the monthlies, whether intercourse take place or not. She did not have this. She, however, did have a bad-smelling discharge. The inference, then, is that this is a carcinoma. Another condition which sometimes causes hemorrhage during coition, is bad laceration of the cervix. In such a case, the slightest touch on the large vascular granulation will cause some bleeding.

Let us look at her color. Where a carcinoma has existed for a long time, there is usually a

change in the complexion, and you get the carcinomatous cachexia. You see the leaden hue of her skin. This is typical. Occasionally it is difficult to distinguish the change of complexion of cancer from that of old malarial troubles.

Passing my finger into the vagina, I come upon a sore which is characteristic. It is crater-like. There is a hard, irregular margin surrounding an excavation, which has on its bottom and sides friable granulations. This is typical of carcinoma.

In making the diagnosis, there is another thing to be remembered. Cancer is exceedingly rare in women who have not borne a child. There are occasional exceptions to this rule, but they are rare. I venture to say that in ninety-nine out of a hundred cases the woman has borne a child. Why is this? It is because some injury has occurred to the cervix; or, as the Germans put it, the cervix has received insults, the insults of coition, but more especially the insults of parturition. The cervix has been lacerated; the delicate lining membrane is kept in a state of constant irritation from rubbing against the vagina as she walks, and from injuries received in coition; it is kept constantly raw, and is liable to degenerate into a cancer. I have frequently proved that the seat of carcinomas was an old laceration of the cervix, by finding the remains of the tear. I find here a notch on the right side posteriorly. The head was probably in the fourth position; the occiput posteriorly and to the right.

Another point—Do women who have not borne children have other kinds of malignant disease? Once in a great while they do. In one case where the woman was said never to have been pregnant, I found carcinoma of the cervix. In very rare cases, I have seen sarcoma of the body of the womb in women who have never had a child. As an aid to diagnosis you should remember that in order to have a cancer of the cervix, the woman must, in the vast majority of cases, have borne a child.

The history of these cases is often this: the menses ceased several years previous to their seeking advice; but several months after the menopause, there was a reappearance of the monthlies. If the woman has borne children, that in the great majority of cases means carcinoma. She usually does not consult a physician, for a feeling of pride comes over her; she thinks that she is getting young again, that rejuvenescence is occurring. She has heard of such cases; she has read of women who have become pregnant at the age of fifty or sixty. [By the way, I saw last week the report of a case where a woman of sixty-two had borne a child.] After a time, the bleeding becomes more marked, and she consults a physician, who finds a carcinoma.

Women are apt to be misled by the fact that they have no pain. They imagine that cancer is accompanied by excruciating pain. In most localities cancer is a very painful affection, but on the cervix it usually does not give rise to more discomfort than is felt at the monthlies. This is because the cervix is an insensible part. After a time, however, when the disease invades the body of the womb, where there are many nerves, she suffers the tortures of the damned; the pain is excruciating. One of my patients had to take

thirty-five grains of morphia a day in order to relieve it. The stomach would get so accustomed to it that to get its effect I had to give it by the bowel, then by hypodermic injection, and then by the mouth again.

The examination that I made has caused a little bleeding. That is one reason why you should never use a speculum in these cases. The finger tells the whole story, and a speculum may cause a hemorrhage difficult to control.

What about the prognosis? It is very unfavorable. Out of all the cases on which I have operated and of which I know the after results, only three have I considered cured. Still I can prolong life, and that is a great thing. In some of the cases on which I have operated, the disease has not returned in the cervix, but in some other part of the body. I have operated on women apparently in the last stages of the disease, so low that you would not give them two weeks lease of life, and have seen them get out of bed and live for over two years. My experience is that the older the woman, the more likely is the operation to be followed by success. In younger women there is more blood in the part, there is a luxuriance of growth, and they are not so apt to be benefited by an operation.

In reference to the treatment. You will find if you read the current literature, that within a year or so, Dr. Freund, a German surgeon, has removed the womb with alleged success for cancer; but the reports which have come from this operation have been so contradictory, the disease has returned so often, and the fatality of the operation itself is so great, that I am led to consider the operation unadvisable except under very exceptional circumstances. It should, I think, be performed only in those cases where the womb is movable; and it is rare that you see cases at this period. The womb is usually fixed, either by inflammatory lymph or by the cancerous material. In this case, the operation would not be advisable, for the uterus is fixed, and the disease has invaded the vagina posteriorly. I once made an appointment to remove the uterus, but a short time before the period fixed, the lady had a convulsion, and an examination of the urine revealed albumen. I therefore did not operate.

The operation which I shall perform to-day, will consist in scraping away the cancerous matter as far as possible and trying to reach healthy structures. The removal of the friable granulations will arrest the bleeding, which may not return. In doing this, I shall use this serrated curette and this fenestrated forceps. In buying a fenestrated forceps, you should get it with the obstetrical lock, so that you can fasten the blades securely together. I am removing a large quantity of this offensive material, and my fingers are going to smell very badly. How shall I get rid of it? I shall first wash them well with soap and water, and then with turpentine, which is very useful under these circumstances. Then I shall again use soap and water, with another go with the turpentine. After this I shall probably immerse them in carbolic water. Permanganate of potassium is an excellent disinfectant, but it has the disadvantage of so staining the hands that one is not presentable for several days after its use.

Now, suppose a woman comes to you and you

diagnosis cancer of the uterus, are you going to say, "Madam, I am very sorry to tell you that you have a cancer."? No, don't you do that. I should not tell even if she asked me to tell her the truth: but in the majority of cases they do not want to know, and will say to you, "Now, doctor, if you find a cancer, don't tell me." No matter how good a woman is, or how fully prepared for the future she may be, the knowledge that she has a cancer is a terrible blow, and she at once gives up, begins to go down hill rapidly, and soon dies. I never, except in very rare instances, tell the patient that she has a cancer; but I always tell some member of the family, or a friend, exactly what is the matter. Suppose the patient asks straight up and down, "Is it a cancer?" You do not want to tell a lie, and you do not want to say that it is a cancer. I get out of it in this way: I say, "This is not that kind of cancer which you understand. This is not a hard cancer like that which comes in the breast, and which is hopeless. You have a bad ulceration of the womb. It is not hopeless; there are cases which are cured." In the case which I have mentioned, where the lady took thirty-five grains of morphia a day, the word "cancer" never passed my lips, nor did it pass hers. None of the members of the family used that word, yet she knew as well as I did that it was a cancer. It was always spoken of as that "bad ulceration." About three years ago, I learned a lesson on this point. I was asked by a physician to see a near relative of his. His suspicion was that it was a cancer. I said to him, "Suppose that this is the case, shall I tell the lady?" He replied, "Yes, she ought to know; tell her by all means." After I had examined and found a carcinoma, I said, "I am very sorry to say that this is malignant," and then went on and told in so many words what the trouble was. She never rallied from that. She made up her mind that her days were numbered, and that there was no use in doing anything, and in a short time she died. I say then, never tell a woman that she has a cancer.

I have now made a funnel-shaped opening, into which I can readily introduce three or four fingers; before, I could barely get one in. I have not gotten into the bladder nor into the peritoneal cavity, but I am afraid if I go further posteriorly, that I shall open Douglas' pouch. I can trace the cancerous tissue to the internal os, but it does not pass to the cavity of the womb.

You see that while there has been some hemorrhage, still it has not been alarming. Sometimes there is unpleasant hemorrhage. During the operation you are not apt to have much hemorrhage if you work rapidly, and quickly get down to healthy tissue. If hemorrhage should occur, do not use Monsel's solution (the sub-sulphate of iron) for it makes plaster-like clots, and so corrugates and contracts the parts that you cannot continue the operation. Under these circumstances, ordinary cider vinegar serves an excellent purpose as a hæmostatic, without the inconveniences of Monsel's solution.

Having removed as much as possible of this friable material, I purpose to apply fuming nitric acid to the raw surface. Usually, I prefer the application of Paquelin's thermo-cautery; but the

instrument is out of order, and I do not think that I can reach all parts as well with the cautery as with a fluid. I apply the acid with a piece of cotton, allow it to remain for a short time, and remove by injecting water. I then again apply the acid. It is not necessary to use alkalies or oil to neutralize the acid. If enough water is injected, it will so dilute the acid that it cannot injure adjacent parts.

There will be but little pain from the operation, but she will probably feel some soreness from the position in which the limbs have been held. When she is put to bed she will receive a suppository of the extract of opium (gr. j).

I am sorry to say that these cases are very common. Cancer is, I think, on the increase; but why it is, I cannot say. The disease more frequently affects the uterus than any other part of the body unless it be the breast.

You see that I have a little wound upon one of my fingers, but I am not afraid of inoculating myself with the cancerous matter, for I am in good health. If I were run down, it might be somewhat hazardous to get such offensive matter on a wound. It is the same with dissecting wounds, which occur usually towards the end of the session and with those who are overworked. This is not the case with venereal disease. No matter whether the health is good or bad, one is liable to be inoculated with syphilis. Nothing would tempt me to thrust my finger into a vagina in which I knew there was a chancre. It was only yesterday that I was asked to take charge of a patient who had a chancre, but I absolutely refused to have anything to do with it. Some years ago I got caught. After examining a case, there appeared on my fingers a sore which would not heal. I showed it to Dr. Agnew, and he pronounced it to be a chancre. For awhile I believe that I was the most unhappy man in Philadelphia. The diagnosis I think was incorrect, for the sore disappeared, simply leaving a scar, and was never followed by any constitutional symptoms. A burnt child dreads the fire, and I cannot be hired to put my finger where I know there is a chancre. Winter before last, in one of the ward classes, after I and a number of the gentlemen had examined the uterus in one of our patients, she called attention to a sore in the vagina, which proved to be a chancre. Some of the gentlemen looked rather frightened, and I cannot say I liked it very well myself.

A number of years ago, I attended a respectable woman in confinement. I then lost sight of her for several years, when she again wished me to attend her. When I called to see her, I noticed that she kept herself wrapped up. As on the previous occasion it had been necessary to use the forceps on account of the narrowness of the pelvis, I was prepared when the head would not come down, to apply the forceps. When I exposed her, I found the nates and buttocks one mass of venereal disease, and her neck was raw from the same trouble. I would have presented any gentleman with a hundred dollars to have applied the forceps and delivered the child. I stripped my arms to the elbows, and thoroughly applied a mixture of carbolic acid and vaseline. I then applied the forceps, using one hand only in the vagina. As soon as they were in position, I ran

out of the room, and carefully washed my hands, and again applied the carbolized vaseline. I then delivered her, and again washed myself with the utmost care. For a number of days I waited anxiously to see what the result would be, but no bad effects followed.

Complete Prolapse of the Womb, with Hypertrophic Elongation of the Supra-Vaginal Portion of the Cervix.

Our next patient is 34 years old, and has had one child, which is near seven months old. Previous to her confinement, she says that she was perfectly well, but now the womb comes outside of her body. I there show you a complete prolapse of the womb.

What has been the history of this? There has been a laceration of the cervix, and consequently the womb received too much blood, for according to the old saying, "Wherever there is irritation, there is flux of blood." As a result of this, involution did not take place, and the parts were left too heavy, and in a plastic condition. The vagina, which, during pregnancy, is thick, did not become thin. The fundus of the womb was kept in place by the suspensory, and partly perhaps by the broad ligaments, while the neck was drawn down by the weight of the vagina and the bladder, and when it had descended far enough, the weight of the urine helped to elongate the cervix. We had then prolapse of the womb with hypertrophic elongation of the supra-vaginal portion of the cervix. That is a pretty long name: the first year students know nothing about it; the second year, a little more perhaps; the third year do not know much about it; and I know very little about it myself.

The supra-vaginal portion of the cervix is that portion of the neck above the attachment of the vagina, and is normally about one inch in length. In the present case it was this portion of the neck which was stretched, but gradually the ligaments holding the fundus in position began to yield, and at last the whole wombescaped from the vulva. It now does not measure more than three inches, but before the fundus began to descend it probably measured five inches.

This pouch containing liquid is the bladder. It always contains residual urine. We empty our bladders by the extrusor muscles. The great extrusor muscles are those of the abdominal wall, but here the abdominal muscles cannot act on the bladder because it is outside of the body. She tells me that in order to urinate she has to replace the bladder, and then the urine only dribbles away. This is because the urethra is sharply curved around the sub-pubic ligament. We have stenosis by angulation. If when you are watering the flowers through a rubber hose, a mischievous boy bends the tube, the water stops flowing, because you have stenosis by angulation, or, in plain old-fashioned English, narrowing by bending. In order to show that this is the bladder, I pass the sound through the urethra, and you see the end of it moving beneath the vaginal mucous membrane.

In treating this patient, the first thing will be to cure the laceration of the cervix. We shall wait a while, and then narrow the aperture of the vagina, and perhaps remove some of the redundant portion of the vagina. The operation is not a

first-class success. There are several ways of operating, but I have not yet decided which method I shall adopt. In the mean time, I shall give her some simple remedy, and advise her to replace the womb and introduce into the vagina a vaginal suppository containing five grains of tannic acid. That will often so contract the vagina as to prevent the uterus from escaping.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, January 1, 1883.
First Vice-President, Dr. T. M. Drysdale, in the chair.

Death from Embolism.

Dr. William Goodell reported the death of the patient from whom he had removed an uterine myo-fibroma. (Case reported by Dr. Baer, in the discussion on Dr. Drysdale's paper, at the meeting of December 7, 1882.) The patient had progressed favorably, but some weeks after the operation, while straining at stool, she had evidently loosened a portion of clot on the proximal side of one of the venous ligatures. It passed into the pulmonary circulation, and quickly caused death.

What is the Proper Management of the Bowels After Perineoraphy?

Dr. Goodell had recently operated, for the relief of lacerated perineum, upon an insane woman, who had been sent to him for that purpose from an asylum. Her insanity commenced after labor, and was probably due to a complete laceration of the perineum, extending two inches up the rectum. It had always been his habit to prevent any action of the bowels during the first week after the operation. This patient, soon after coming out from the influence of the anæsthetic, tore off the bandage from her knees, removed the catheter, and by severe straining efforts, secured a movement from the bowels. As she could not be controlled, laxatives were given to secure liquid stools and avoid straining. The patient walked freely about the ward from the day of operation. The doctor expected the operation to be a failure under such circumstances; but to his surprise, on removing the sutures he found that in the rectal portion and the important part of the perineum, union had taken place.

His attention has been called by this case to the question of the advisability of keeping the bowels constipated after this operation. He intends to try the effect of laxatives in future cases.

Dr. R. P. Harris reported the case of a woman who, after the operation of perineoraphy, would strain, and her efforts at defecation opened the wound to nearly its original extent. In a second operation on the same patient, the bowels were kept free and union was perfect.

Dr. E. E. Montgomery, after operating for lacerated perineum, does not use a catheter, but allows the patient to pass her water, as he does not consider healthy urine disadvantageous for a wound. He has been in the habit of using compound liquorice powder to keep the stools liquid. He has had good success in both primary and second-

any operations upon the perineum where the rectum was involved.

The following members were then elected

Officers for 1883.

President, Dr. Richard A. Cleemann.

Vice-Presidents, Drs. B. F. Baer, and W. T. Taylor.

Secretary, Dr. W. H. H. Githens.

Treasurer, Dr. Alfred Whelen.

Librarian and Curator, Dr. E. E. Montgomery.

Publication Committee, Drs. John H. Packard, Elliott Richardson, James V. Ingham, B. F. Baer. *Counsellors*, Drs. R. P. Harris, L. D. Harlow, Wm. Goodell, T. M. Drysdale.

Library Committee, Drs. Horace Williams, D. M. Cheston.

Committee on Proceedings, Drs. A. H. Smith, E. E. Montgomery.

Stated Meeting, Thursday, February 1st, 1883.

The President, Dr. R. A. Cleemann, in the chair.

Dr. B. F. Baer read the analysis of twenty-seven operations for the restoration of the Lacerated Cervix-Uteri, with special reference to the effect on Sterility and Labor.

In the discussion which followed the reading of Dr. Playfair's paper on "Trachelorrhaphy, or Emmet's Operation," before the Obstetrical Society of London, on March 1, 1882, Dr. Herman, in the course of his remarks, said that "The American literature on the subject consisted mostly of general statements. Few writers had published cases, and the cases were mostly complicated ones." There is some force in these words. But to avoid a monotonous repetition, it is desirable only to publish such as are strongly illustrative of the class to which they belong, or such as bear directly upon any point which may be under discussion.

In the *American Journal of Obstetrics* for January, 1883, Dr. P. J. Murphy, of Washington, D. C., makes some "Observations on the Effects of Trachelorrhaphy on Fertility and Parturition," and comes to the conclusion "That repair of lacerations of the cervix uteri is usually followed by sterility." Now, there is no doubt of the truth of this statement, so far as it goes; but I think that he ought rather to have said that in those cases in which sterility followed the operation, that condition also preceded the repair of the cervix in the majority of instances, either as a result of the laceration itself, or of its effects on the uterus and its appendages; and that the operation was not the cause of the sterility, but that it simply failed to cure it.

The only way to arrive at anything like a correct conclusion on this subject, is to take a number of cases (it need not be large) and analyze them, and this I purpose doing with mine.

Of the twenty-seven cases in which I have made the operation, six were either widows, or had reached or passed the menopause, and must therefore be excluded from the analysis. This leaves twenty-one cases to be reported upon in this inquiry. Of these twenty-one cases, thirteen had been sterile from five to sixteen years previous to the operation, and I think, for reasons which I will give farther on, that they ought also to be classed as beyond the probability of becoming pregnant. In the remaining eight cases,

pregnancy had occurred within five years, but had resulted in abortion in five. In twelve of the twenty-one cases, from one to five abortions had occurred in each subsequently to the occurrence of the laceration. This gives abundant proof of the ill-effects of the lesion and its results, subinvolution, chronic hypertrophy, cellulitis, oöphoritis, etc., on fertility.

Is the assertion that sterility usually follows, as a result of the operation, correct? I do not think so; provided, of course, that the operation was properly made, that the os was not made too small, and immediate union followed the coaptation of the parts, so that there was left the minimum amount of cicatricial tissue to interfere with the normal resiliency of the cervix.

The oftener abortion occurs, as a rule, the greater and more persistent will be the histological changes in the uterus and its appendages, which finally result in sterility.

The majority of cases in which the operation has been made have been of long standing, because the operation is new, and there were many old cases of so-called "ulceration" with chronic hypertrophy, waiting ready to be experimented upon with this, as they had been before with many other old and new remedies.

Is this last new remedy followed by any greater success than the old in the reduction of the size of a large uterine body, which has become hard and fibrous from connective tissue hyperplasia? I think not; and hence its failure to cure sterility of long standing, from this cause. But, for the cure of certain cases of hypertrophy of the cervix, inflammation, ectropion and abrasion of the mucous membrane, with their local and remote symptoms, and possibly, even probably, preventing epithelioma, and in the more recent cases for the cure of subinvolution, abortion, and sterility, the operation is an immense stride in advance of the old way of destroying the tissues of the cervix by amputation, or by the application of the hot iron or the potential cauteries. It is an advance, because it restores the cervix instead of destroying it.

The following case proves, I think, that abortion may result from laceration of the cervix, although none of the usual inflammatory consequences of the lesion are present.

Case 1.—Mrs. M. L., *æt.* 30, consulted me in January, 1881. She was delivered of her first child two years previously. The labor was rapid. The child was fully developed and vigorous. There was nothing unusual in the puerperal period, and she seemed to be well. Ten months after the birth of the first child she became again pregnant. Between the second and third months of gestation the product of conception was expelled with little pain, but it was followed by severe hemorrhage. Within three months, she was again pregnant, and aborted at about the same time and manner as previously. This was followed within six months afterwards by a third pregnancy, and abortion under similar circumstances. The last occurred about two months before she consulted me. She had absolutely no symptoms of uterine disease, such as leucorrhœa, menorrhagia, and the pain which always results from congestion and hypertrophy of the uterus; and expressed herself as feeling as well as ever

she had in her life. There was no evidence, whatever, of syphilitic infection, either in the patient herself or in her husband. They are both robust and well developed.

Examination.—The perineum and vagina were normal. The uterus was in normal position; it was neither congested nor enlarged; but the cervix was lacerated on the left side to a point beyond the vaginal attachment, apparently approaching and involving the fibres of the internal os. On the right side there was a mere fissure only. There was no hypertrophy, eversion, or abrasion of the mucous membrane. The sound passed to a depth of two and a half inches. I expressed the opinion that the lacerated cervix and the abortions stood in the relation of cause and effect; and I advised an operation for the restoration of the torn cervix.

On March 10, 1881, I denuded the surfaces, being careful to remove very little tissue, and to freshen the edges as far up towards the internal os as possible. I then placed six carbolized catgut sutures, and clamped them with shot. I used the gut suture here in preference to the silver wire, because, as the cervix was not large, and the tear principally unilateral, there would not be much tension, and for the additional reason that I especially did not want any cutting of the tissues by the sutures, which is more apt to occur when wire is used. Another advantage of gut suture is that the line of union need not be disturbed by the removal of the stitches. On the seventh day after the operation, I inspected the cervix through Sims' speculum, and found the sutures all *in situ*, though they were partially absorbed. Union was perfect. Two days afterwards the shot were lying loose in the vagina. There had not been the slightest discharge from the united surfaces since the operation.

On June 3, 1881, the patient reported that she had not menstruated for seven weeks, and there was every indication that she was pregnant. A week later I was requested to visit her. I was much chagrined to find when I arrived that she had aborted. This was very discouraging, but I found some comfort in the character of this abortion. More pain attended the expulsion, and less hemorrhage followed it, than on the previous occasions. This I ascribed to the restoration of the symmetry of the cervix, and its better retentive power.

On October 9, 1881, she reported that she was about two months pregnant, and feeling well; and on May 7, 1882, she was delivered at full term of a fully developed, healthy boy, after a perfectly normal labor of six hours' duration. Examination two months afterwards revealed not the slightest laceration of the cervix. The mother and child are both well.

Case 2.—Mrs. M. R., æt. 21 years, consulted me in May, 1878. She had been delivered eight months before of her first child; the labor being tedious, was terminated with the aid of the forceps. The puerperal period was also tedious, and she had ever since been troubled with pain in the hypogastric and lumbar regions, together with a profuse leucorrhœa. Coition was painful, and followed by slight hemorrhage. She was anemic, and had lost flesh.

Physical Exploration.—The perineum was slightly

lacerated, and the vagina relaxed. The cervix uteri was pressing low down on the pelvic floor, and lacerated, bilaterally, but to a greater degree on the left than on the right side. The tissues were soft from engorgement, and the mucous lining of the cervical canal greatly hypertrophied, everted, and abraded of its epithelial covering, so that it bled on the slightest touch. The uterine body was likewise congested and tender. The sound gave a measurement of minus three inches.

I treated this patient locally and constitutionally for almost a year, with marked general improvement, and although the local condition would improve, the benefit was only temporary. On April 30, 1879, I made the operation for lacerated cervix, placing seven silver sutures. Perfect union resulted.

Three months after the operation she became pregnant, and was delivered spontaneously at full term. The labor was so easy that delivery occurred before the arrival of the physician. Two months after the labor she called at my office, at my request, and I found the cervix healthy, although there was a very slight fissure on the left side. She stated that she had been well since the operation.

Case 3.—Mrs. A. B., æt. 34 years, was sent to me in July, 1880. She had had eight children, the youngest of which was six months of age. She stated that she always menstruated during lactation, and became pregnant when her children were about eight months old. Since the birth of the last child she had had metrorrhagia every three weeks, lasting one week, and a profuse leucorrhœa for years. She complained of pain in the lumbar region, with a heavy dragging sensation in the pelvis and on the top of the head. She was emaciated, and so pale that she appeared bloodless. She had become hysterical.

Touch.—The perineum and vagina were very much relaxed. The cervix uteri was far back, and presented a nodular surface, the result of three deep rents in its tissue, one of them extending through the centre of the anterior lip, flush with the vaginal junction. There was marked ectropion of the mucous membrane, with abrasion. The body of the uterus was anteverted, and only slightly larger than normal.

I placed this patient upon the "rest treatment" of Dr. S. Weir Mitchell (modified somewhat to suit the circumstances), in addition to the necessary local treatment. Her improvement was very marked, and on October 10, 1880, three months after she first came under my care, I operated for the laceration, and secured immediate union.

Under the date of October 27, 1881, a year from the date of the operation, I find this note in my case-book: "Returns to-day at my request for examination. She has improved so much in appearance that I scarcely knew her, and she states that she has been well since a short time after the operation. The cervix is normal."

I recently received from my friend, Dr. Wm. L. Taylor, the following note concerning this lady:

"DEAR DOCTOR: In answer to your inquiry regarding Mrs. B., I will state that she was confined six weeks ago. The labor was natural, and if it differed in any way from her former labors, it was more rapid. I examined the cervix to-day, and found the external os patulous, but no laceration."

(To be continued.)

EDITORIAL DEPARTMENT.

PERISCOPE.

Electrical Stimulation of the Uterus.

The *Lancet* says that the influence of electricity on the uterus, whether empty or gravid, is a point on which authors have made various statements. The difference of opinion may be due to the circumstance that the conclusions have been drawn from the somewhat uncertain field of clinical observation. M. Dembo, in a note presented to the Académie des Sciences by M. Vulpian, has endeavored to decide the question by experiments on animals. His observations at present relate only to the non-gravid condition. In the rabbit, direct faradization of the uterus or of one of its cornua causes a contraction at the point to which it is applied, and which extends for a distance of about twenty millimetres, but never reaches the other cornu. If one electrode is applied to each cornu, both can be made to contract in the neighborhood of the poles, but not in the interval between them. Very different, however, is the effect when the application is made to the vagina. If both electrodes are applied to the vesical wall of the vagina, a manifest contraction is produced in both parts of the uterus, vermicular in character, passing from below upwards. If the application be made to the lateral portions of the vaginal wall, a contraction is produced only in the corresponding cornu. Local contractions on the corresponding side can be produced by placing the electrode on certain points in the broad ligament, but the contraction never extends to the whole uterus. It is impossible to produce contraction of the non-gravid uterus by faradization applied through the abdominal wall. The excitability of the uterus of the rabbit was found to vary according to the age of the animal, and according to whether it had borne young or not. That of a young animal is so irritable that manifest contractions are excited by mere exposure to the air, but in old rabbits the uterus is much less susceptible. In some dogs and cats no contraction of the empty uterus could be obtained by faradization, in others slight contractions with distinct pallor were produced. Faradization of the vaginal wall caused pallor of the mucous membrane, and also of the whole uterus, due apparently to contraction of the vessels, but no contraction of the substance of the uterus. Frankenhauser found that stimulation of the aortic plexus caused a manifest contraction of both cornua, and it is highly probable that an analogous nervous plexus is situated in the vesical wall of the vagina. The observations were made on animals under the influence of either chloral or curara.

Radical Cure of Inguinal Hernia.

Dr. James Whitson reports the following case in the *Medical Times and Gazette*, January 27, 1883:

John McB., aged fifty-six, laborer, was admitted

on October 18, 1882, to the Royal Infirmary, suffering from what was supposed to be a strangulated inguinal hernia, which, however, Mr. Greenhill, house-surgeon, succeeded in reducing, without difficulty, the ring being a wide one, and the distance, in consequence, between its pillars being very considerable. The patient having afterwards expressed a desire to be relieved of his infirmity, which was a constant source of annoyance as well as danger to him, I resolved to perform an operation for the radical cure of hernia; but, before doing so, I thought it expedient to give him a few days' rest in bed, so that his bowels might be carefully regulated, and any shock which he had suffered from on admission might have had time to pass off.

On October 27 the patient was put under chloroform, the pubes carefully shaved, and, with the kind assistance of my friend, Mr. Clark, I proceeded to operate by first of all transfixing a fold of skin over the inguinal ring, and cutting outwards. The various structures between the skin and the mouth of the canal were successfully divided on a director until the sac was reached, when it was opened into, and a large portion of it removed. Wood's needle, threaded with the strongest chromicised catgut, was then passed through the upper and outer side of the ring, carried over towards the inner pillar, and when brought into contact with the skin on that side, the latter was pulled away in the direction of the mesian line, so as to permit of the exist of the point of the needle at the opening already made. Three separate sutures of catgut were introduced in this way; and the cut edges of the sac were stitched together with moderately-sized gut. The pillars of the ring were then firmly approximated by tightening the sutures, and securing them with reef-knots. A decalcified drainage-tube, threaded with horse-hair, was inserted into the wound, the margins of which were brought together with two button sutures, and accurately apposed by means of several stitches of fine gut. Protective plaster and gauze were next applied in the usual way, and an elastic bandage assisted in keeping the whole in excellent position. The dressings were changed on the second day, when the hair was withdrawn from the drainage-tube, and union by first intention had taken place along the whole line of incision, with the exception of the lowest point, where a necessary aperture for the exit of the discharge remained. It is needless to give further particulars of the progress of the case, as the wound followed a truly aseptic course, and the patient made an excellent recovery. He was dismissed, cured, on December 2, 1882.

Hysteria in Young Boys.

From the *Med. Times and Gazette*, January 13, 1883, we learn that M. Charcot has recently (*Progrès Médical*, 50 and 51, 1882) published a lecture devoted to proving that hysteria in its ordinary and typical form may occur in young

boys. We should hardly have thought that a separate lecture was needed to demonstrate the fact. Even amongst such a non-emotional set of beings as the English are, we yet have ample proofs afforded us that boys can and do have hysteria, even when mere infants, as Dr. Barlow has on more than one occasion shown. One of the patients whom M. Charcot showed to his class (and we need only quote this one) was a young Hebrew, aged thirteen, who had been brought by a fond but exceedingly foolish father from Russia to Paris. The history of his malady was that he had a persistent headache, a spot of exaggerated sensibility on the top, and an attack coming on every evening about the same time, consisting of an increase in the headache, noises in the ears, and a sensation of thoracic constriction. At other times, on the right side there was analgesia to a prick, to cold, and to faradisation; taste, smell, and hearing were diminished; and there was contraction of the field of vision on this side, as also some impairment of color-vision. During the attack, he used to lie down on a couch doubled up, with his hands up to his head in a fixed position, his eyes filled with tears. In a few minutes the attack would pass off without any of the ordinary manifestations of the termination of a hysterical attack. The father, unintentionally, doubtless, adopted the best means to insure an occurrence of the attacks; for as the usual time of their appearance drew near, he would pull out his watch and begin asking the boy how he felt, and expressing sympathy for him in his sufferings. As might be expected, a speedy cure was effected when the boy was quite separated from his father, though it was about a month before the amblyopia had finally disappeared.

Hydrargyrum Formidatum in Syphilis.

The *Medical Times and Gazette*, January 6, 1883, says that Professor Liebreich brought forward, at the last meeting but one of the Berlin Medical Society, a new drug for the treatment of syphilis by the subcutaneous method. This drug rejoices in the name of hydrargyrum formidatum, and is, therefore, merely a different form of the old cure for syphilis. The mode of its preparation was not stated; chemically, it belongs to the amide group, in whose structure the monovalent amidogen (NH_2) plays an important part. Liebreich was led to think of this new preparation from the notion that the ordinary amides of the body, of which urea may be regarded as the principal one, pass out of the organism in an undecomposed state; when, however, an amide is in combination with a metal, decomposition readily occurs, and the metal is reduced and deposited. Liebreich repeated his experiments before the Society, and showed that these conjectures were quite true for the metal mercury. It is supposed, therefore, that the formamide of mercury, after the hypodermic injection, undergoes disintegration; and so the mercury is set free, and is able to exert its well-known power over the lesions of syphilis. The preparation is easily soluble in water, is of neutral reaction, does not coagulate albumen, is not precipitated by caustic soda, and the presence of mercury can be demonstrated by means of sulphide of potassium. The drug, when injected

under the skin, produces its effects very surely and rapidly. This is not regarded as a disadvantage, for the medicine is said to be easily borne, and has never produced salivation in Liebreich's hands. There is very little pain attendant on the injection, which has never excited any inflammation. From a half to a whole of a Pravaz syringe-ful (a 1 per cent. watery solution) may be injected twice or thrice daily. Liebreich looks on the preparation as the best we yet have for subcutaneous injection.

Teeth Injured by Tobacco.

In the *Southern Dental Journal*, for January, 1883, John G. Harper, D. D. S., writes as follows:

"I was taught that the use of tobacco in any form was not injurious to the teeth, and in all the literature of the profession I have found nothing alluding to what I desire to present to the profession; namely, the evil effects upon the teeth, caused by the constant use of tobacco. My attention was first drawn to this evil just one year ago this month, when I was filling the teeth of a patient who has for years been in the habit of smoking and chewing a great deal of tobacco.

"The injurious effects are not very noticeable until the person has been using the weed for about fifteen years, but the use of the pipe to excess will show its injurious effects in less time. Tobacco chewing is the most injurious, as the tobacco acts as an irritant in two ways, mechanically and by its properties—mechanically by particles of the tobacco being forced between the gums and the teeth. We have proofs of the irritable effects of tobacco in snuff. The direct effect of using tobacco is the recession of the gums of all the teeth, but more especially those on the side of the mouth used most in chewing the tobacco. The sequel to this recession may cause the loss of one or more teeth, by a diseased condition of the pulp, resulting from its being irritated by having the neck of the tooth and the root exposed to thermal changes in food and in the air we breathe. Exostosis and calcification may result.

"Tobacco chewers' teeth wear away on the grinding surface rapidly, caused by the gritty substances naturally entering into the tobacco. The gums recede and are red and congested, and underneath the gum a narrow line of dark tartar is nearly always present, and particles may be found still further toward the apex of the tooth."

Hegar's Operation.

From the *New York Med. Jour.*, January 27, 1883, we note that Dr. C. C. Lee, the President of the New York Obstetrical Society, related the following case: An unmarried woman, aged thirty-six years, was sent to the Women's Hospital by Dr. Streeter, of Watertown, to have oöphorectomy performed for the relief of symptoms due to a large multilocular fibroid tumor of the uterus. She had been suffering from menorrhagia and dysmenorrhœa for years, and had been unable to obtain relief. The tumor was as large as a foetus at the seventh month, lay principally on the right side of the abdominal cavity, and extended as high up as the umbilicus. The uterus could not have been extirpated without imminent danger to

life. After an unsuccessful trial of medicinal treatment for a month, it was decided at a consultation of the surgeons of the hospital, that Hegar's operation should be performed. The President removed the Fallopian tube on one side and both ovaries. The case was progressing favorably since the operation. The right ovary was bound down by adhesions, and extremely difficult to remove. Where adhesions were not present, however, the operation was not a difficult one. This was the third time it had been resorted to at the Woman's Hospital within a month—twice by Dr. Thomas, and once by himself. The patients were doing well. According to the statistics of the operation, as given in the "American Journal of Obstetrics," January, 1880, out of one hundred and twenty cases only twenty-eight deaths had occurred. The success of the operation in relieving menorrhagia and dysmenorrhœa had been so great, and the dangers attending its performance had been so small, that the President thought it should be resorted to in these cases more frequently than had been done in the past.

An Epidemic of Diphtheria from Infected Milk.

Dr. Morrell Mackenzie has favored the *British Medical Journal*, January 20, 1883, with the following note of a severe but limited epidemic of diphtheria recently raging at Hendon, which has been traced by himself and Dr. Cameron to the infection of the milk supply. Although in some previous epidemics a strong suspicion has been entertained that milk was the vehicle of the poison, the inquiries have generally been made so long after the occurrence that it has been difficult to arrive at any certain result. In this instance, however, the facts appear to be conclusive. Fifteen persons were attacked on a single day, the disease in every case being a typical example of what French writers call *diphthérie d'emblée*. All the patients received their milk from the same vendor, and no other case occurred among the comparatively large population supplied by other dairymen. It has been discovered that the purveyor of the tainted milk, washed his cans in water derived from a brook which contains a large amount of sewage matter. Indeed, the whole of the Church End district of Hendon is drained by an open ditch into the Brent, and this ditch passes slightly above and in close proximity to the brook used by the dairyman in question. In the Tenterden Park district, every household made use of the tainted milk except two. One of these families had cows of their own, and the other had thrown away the milk supplied to them the day before the outbreak began, because it was thought "it looked bad." These two were the only houses in the Tenterden Park district which altogether escaped infection.

Compensatory Hypertrophy of the Kidney.

From the *British Med. Jour.*, January 13, 1883, we learn that Prof. Golgi has recently communicated to the Lombardy Institute the results of his experiments on this subject, showing the changes in one kidney when the other has been removed. The author points out that Valentin, in 1839, basing his opinion on experiments, held that the increase in size and weight of the organ was due

only to the increase of its contents through dilatation of the blood-vessels and the canaliculi. In 1871, Rosenstein supported almost the same view, attributing only a trivial portion of the augmentation to increase of the epithelium, or of the interstitial tissue. Of recent authors, Ribbert held, but without proving it, that proliferation of the epithelium accompanies the dilatation of the canaliculi. Tizzoni and Pisenti, on the other hand, asserted that the epithelium of the tubules was altogether passive. These last authors, however, had overlooked the only criterion by which it was possible to say whether the cells were passive or not, namely, the series of changes they undergo in multiplying. Taking these changes as his guide, Professor Golgi found that the increase of a kidney after the removal of its fellow should be ascribed, at least in part, to a development of the pre-existing glandular tissue. Whether new canaliculi are formed, he does not as yet feel authorized to say; and on this point he thinks further researches are desirable.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—An edifying and unique contribution to medical literature comes to us in the form of a reprint from the *American Journal of the Medical Sciences*. Dr. John L. Atlee, of Lancaster, contributes a valuable article on a case of Strangulated Hernia, complicated by a very extraordinary diseased spermatic cord; his son, Walter F., a case of ovariectomy, in which the expanded bladder was wounded, with recovery; and his grandson, Louis W., a case of Congenital Cyst of the Back of the Head, with serous contents, its cavity unconnected with that of the skull.

—An excellent and forcible article in favor of cremation is the address on "The Disposal of the Dead," read before the American Public Health Association, by Dr. W. H. Curtis, of Chicago, which we receive as a reprint from the Public Health Papers of the Association.

—The Board of Trustees appointed at the last annual meeting of the American Medical Association, charged with the duty of agreeing upon the plan of a weekly medical journal to take the place of the annual volume of Transactions, and to ascertain how far pledges for its pecuniary support could be obtained from the profession, held a regular meeting at Chicago, on the 17th day of January, 1883. They reported that they believed the proposed plan could be carried out.

—The contents of *Lippincott's Magazine* for March are unusually varied, and include several articles of special interest. Professor James D.

Butler has an apparently exhaustive paper on the "Portraits of Columbus." "Invalid Life in the South" sums up the experiences of five years spent in the recovery of health, and contains much information and many suggestions that cannot fail to be useful to those who are in search of a genial climate and other favorable conditions with the like object.

—In a reprint on the medical relations of the various forms of food adulteration in vogue in this country, Dr. Henry Leffman, of this city, who is a competent chemist, makes the comforting assurance:

I cannot let this opportunity pass without stating my convictions that at present no urgent necessity exists for specific legislation in reference to food adulteration. I do not agree with the view that extensive disease is caused by the practice; and even if such effect did occur, I feel certain that, under the principles of common law, ample protection to the community exists, as soon as the attention of the prosecuting officers is directed to the matter.

—The "Proceedings of the Naval Medical Society," Vol. I., No. 1, makes a neat pamphlet of 32 pages. It is taken up with papers on "Etiology and its relation to Line of Duty," matters of purely technical interest. The following are the officers of this Society at present: President, Albert L. Gihon, M. D.; Vice-President, John M. Browne, M. D.; Secretary, James M. Flint, M. D.; Business Committee, Thomas J. Turner, M. D., Adolph A. Hoehling, M. D., Thomas H. Streets, M. D.

—A broadside "Consultation Chart" of the eye symptoms and eye complications in general diseases has been prepared by Dr. Henry G. Comwell, of Columbus, Ohio. It appears to be full and accurate, and is well worth the practitioner's attention.

—To the literature of tuberculosis we add the following titles: "Tuberculosis as Manifested in the Larynx," a report of a number of instructive cases by Dr. J. Solis-Cohen, of this city; and "A Simple Solution of the Mystery of Tubercles," by Dr. Rollin R. Gregg, of Buffalo, N. Y., whose peculiar views we have previously referred to.

—Dr. Douglas Graham has republished through J. H. Vail & Co., New York city, a popular description of Massage and its uses, originally written for the *Popular Science Monthly*. It is a succinct and accurate essay on the subject.

—A pamphlet of interest to botanists is one entitled "The New Botany," a lecture on the best method of teaching the science, by W. J. Beal, M. Sc., Ph. D., Professor of Botany in

Michigan Agricultural College, Lansing, Mich. Second edition, revised by the author, price 25 cents. Published by Chas. H. Marot, 814 Chestnut street, Philadelphia.

BOOK NOTICES.

Sanitary and Statistical Report of the Surgeon-General of the Navy for the year 1880, Washington, 1882. 8vo. pp. 469.

It is rather late to receive a report for 1880, but better late than never. Moreover, it is a very good report—the best we have ever seen from that Bureau—and this makes amends. The opportunities for observation of the navy surgeons are unusual, and they make intelligent use of them. The volume is full of sanitary notices and local studies, which give pleasant reading to all who take an interest in medicine as a broad science. It deserves a place on the shelf of many who have never been to sea, and never expect to go.

A Practical Treatise on Diseases of the Skin. By James Nevil Hyde, A. M., M. D., etc. H. C. Lea's Son & Co., Cloth, 8vo., pp. 571.

The author presents here a work which does credit to his study of the subject, but we cannot say that we have found in its pages much or any fruit of original research. It impresses us as a compilation—a fair and judicious compilation—but not meriting a higher praise. We do not see that any particularly new light is thrown upon any of the vexed questions in dermatology, nor is the therapeutics of the branch enlarged by any discoveries.

To those who would like a compact treatise presenting what is known in this specialty, we can recommend the one before us; but the student of the branch who is already familiar with its literature will scarcely find it to repay him to read Dr. Hyde's book.

An Essay on the Breeding and Management of Draught Horses. By Richard S. Reynolds, M. R. C. V. S. London: Billiere, Tindall & Cox. 1 vol., Cloth, 8vo., pp. 104. Price, \$1.25.

We have here one of those able monographs in veterinary science which show how much more thoroughly that department is studied in England than in this country. It is an excellent physiological treatise on the methods of improving the particular breed of horses under discussion, and though written for the latitude of Great Britain, the American reader can glean from it many valuable hints. For sale at the office of the MEDICAL AND SURGICAL REPORTER.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

THE WEIR-MITCHELL TREATMENT.

Every physician who knows anything at all, knows very well that Dr. S. Weir-Mitchell, of this city, has established upon a rational foundation his method of treatment of certain nervous disorders, by means of forced feeding and forced utilization of the food so ingested.

Dr. Playfair, of London, has been using the same methods now for some eighteen months, and his successes fully coincide with Dr. Mitchell's.

The case best suited for systematic Weir-Mitchell treatment is the worn and wasted, often bedridden woman, who has broken down, either from some sudden shock, such as grief, or money losses, or excessive mental or bodily strain, beginning with simple debility more and more yielded to, until at last all power of effort is lost. Coincident with this is the total loss of appetite, the profound anæmia, and the consequent wasting of the tissues.

Then follow the graver forms of hysterical disease, such as paresis, or paralysis, vomiting, disorder of motion, hystero-epilepsy, and many others, which constitute the despair of the physician.

The principal elements in the systematic management of these cases are:

1. The removal of the patient from unhealthy home influences, and the placing her at absolute rest.

2. The production of muscular waste, and the consequent possibility of assimilating food, by what have been called "mechanical tonics," viz., prolonged movement and massage of the muscles by a trained shampooer, and muscular contractions produced by electricity.

3. Supplying the waste so produced by regular and excessive feeding, so that the whole system, and the nervous system in particular, shall be nourished in spite of the patient.

Since one of the chief elements in this treatment is the removal of the patient to a hospital, thus isolating her from the morbid influence of well-meaning but injurious commiseration of anxious friends and relatives, it is evident that its application is restricted to cities, and cannot be

well carried out in country districts, where no such homes or hospitals exist.

The experience of these two eminent gentlemen is highly satisfactory, and it behooves us all to give great heed to these evidently valuable therapeutic measures.

THE ELECTRIC LIGHT IN SURGERY.

It would seem that we are on the eve of an exceedingly important development of the practical application of the electric light to aid the surgeon in many of his dark and narrow ways. More than a year ago, Sir Henry Thompson explored the bladder by means of the electric light; and now Leitz, of Vienna, is devising instruments for illuminating the throat, posterior nares, bladder, uterus, etc.

The aid that this light will afford us in detecting diseased conditions of these obscure cavities is simply incalculable. It will bring their hidden recesses as clearly and distinctly to our view as is now the external surface of the body. Dr. Thomas Oliver has recently demonstrated afresh the practicability of this use of electricity. He says:

"Having at the present time a patient in the infirmary who is suffering from hydatid disease of the liver, on whom the operation of abdominal section with incision of the liver had been performed, giving exit to about seven pints and a half of pus—I took advantage of the opportunity, and succeeded in lighting up the interior of the cyst by means of the electric light. For this purpose Mr. Payne devised and constructed a brass tube, electro-plated, nine and a half inches in length, and eleven-sixteenths of an inch in diameter externally. One end of this tube was funnel-shaped, and the other was closed by a piece of glass; down this tube was inserted a narrow cylinder, which carried a Swan's lamp and the electric wires. This tube, with its glazed extremity, was smeared with carbolized-oil, although, in future, I shall use carbolized glycerine for the window of the tube, and, with gentle pressure, I succeeded in passing it through the abdominal incision into the interior of the liver. The lamp was at once lit, and I had the pleasure of observing a greyish-red condition of the wall of the cyst, studded across which were numerous yellow-white spots, evidently pus; a slight oozing, or sweating, was also noticed on the wall of the cavity. The illumination of the interior of the liver by means of the electric light was in every way satisfactory and successful; and, although it is of little aid in the treatment of the case in question, it has shown us that the lighting up of internal cavities is not only a possibility, but a

matter of comparative ease. With the extremely small size of the Swan's lamp required (it is not much larger than an ordinary bean), and which gives a light equivalent to that from three candles, and with the improved instruments which Mr. Payne is devising, I see how the electric light might become useful in operations for vesico-vaginal, or recto-vaginal, fistula, and in certain diseases of the bladder."

BILLROTH ON EMPYEMA.

Billroth's views on this subject are justly entitled to attentive consideration. He does not believe that either tuberculosis or caries of the ribs are common sequences of empyema, but rather inclines to the view that death is more common from other accidents and from lardaceous degenerations.

He does not believe that the results of operations for this disease are any more favorable since than before the introduction of Listerism. Fifteen cases treated in his clinic since 1876, by free openings and various forms of antiseptic dressings, terminated as follows: Of three (empyema associated with tubercular disease), two died and the third was lost sight of. Of ten (the result of simple pleurisy), three died, one did well for a time, but died within a year; four did well for some months, but were then lost sight of; in three, while there was some improvement, the fistulas remained open and discharging two years after the operation. Of the last two (of traumatic origin), one recovered apparently completely in nine months; the latter improved, but was not healed after eighteen months.

Of fifteen cases operated on by Weinlechner & Billroth, in only two was a definite and permanent cure effected. The *Medical Times and Gazette*, January 27, 1883, from which we learn these facts, concludes that the statement of opinion by Billroth, that antiseptic treatment of the discharging empyema is without influence in the prevention of septic serous inflammations, is worthy of all attention, as proceeding from him; but we have seen isolated cases of enormous empyema in children, even when offensive to the nostril, do remarkably well with proper antiseptic dressings. We are glad that Dr. Fraenkel has put this series

of cases on record, and we hope that his excellent example will be followed both at home and abroad. More information and statistics on the results of cases treated with Listerism are greatly to be desired.

THE PREVENTION OF HYDROPHOBIA.

In 1862 Bourrel suggested that when the permanent teeth of a dog are well grown, the incisors and canine teeth can be blunted so as to render it impossible for a dog to inflict wounds on men or animals which might lead to inoculation with the virus of rabies. At the time, his suggestion was much ridiculed, one journal suggesting that all dogs should be provided with false teeth. The question has been revived in the *Medical Press and Circular*, January 17, 1883, by "a member of the Sanitary Institute of Great Britain."

"In general," says M. Bourrel, "it is a sharp pinching produced by the front teeth that causes inoculation; the skin is torn, or the bite draws blood. By blunting, or resection, sixteen obtuse surfaces are substituted for sixteen sharp points. Sporting dogs in the habit of tearing the game have been prevented from doing so by this measure, while the furious disposition of some dogs, such as watch-dogs, which render them dangerous to every one, was softened, and brutes which would have to be destroyed were consequently allowed to live. Terriers have not ceased to kill rats after this blunting; they have only lost their power to kill cats, which is a happy result. The same operation disarms those bull-dogs that certain individuals have the discreditable passion of exciting to fight; pet dogs have been operated upon without any inconvenience."

The suggestion seems to us a very practical one, and we heartily commend it.

It is too much to hope that legislation could compel compliance with it, but we give it publicity in this country, in the hope that owners of dogs will voluntarily resort to it, especially since it is expressly stated that it does not injure the animal.

The argument of "cruelty to animals" cannot be validly urged against it, since it is much less repellent than the clipping of the ears or tail, so commonly resorted to.

Hydrophobia is such a terrible disease when contracted, that so simple and commonplace a precaution ought not to be neglected; but its universal application will require the co-operation of the people.

FRENCH AND GERMAN SCIENTISTS.

One of the benefits to science of the animosities created by the Franco-Prussian war has been but lately made manifest. At the late International Congress of Hygiene, at Geneva, M. Pasteur, the celebrated French scientist, made an attack on Koch, the distinguished German investigator.

The latter, owing to want of familiarity with the language, postponed his reply, which he has now made in a pamphlet published at Berlin. He claims for himself the discovery of the cause of splenic fever (Pasteur's great stronghold), because he showed the development of anthrax spores and their relation to the disease in 1876, while Pasteur did not publish his discoveries until 1877. He denies the high value of preventive inoculation, in such diseases as fowl cholera and anthrax, claimed by Pasteur.

So on, throughout the pamphlet, he takes occasion to belittle and doubt the conclusions of the Frenchman.

This paper will naturally irritate the excitable French blood, and the gauntlet having been thrown down, the thinking world will no doubt be afforded much food for reflection ere the termination of this scientific duel between the illustrious and sanguine Frenchman and the distinguished and phlegmatic German.

So goes the world, and it is well that it does, for by these very conflicts of valuable opinions we are saved from accepting as settled facts the teachings of any one, until they have been tested and thoroughly criticised. It was said just after the close of the war that the feeling created by it would redound to the benefit of science, and it would seem as though the prediction were to be verified.

SANITARY LECTURES.

The Chicago Medical College is giving its students an extended course of lectures on State medicine, which embrace information concerning the introduction, spread, and restriction of small-pox; vaccination, and the propagation of vaccine virus; the prevention of epidemic and pestilential diseases; and sanitary living as applied to

the individual. This last comprises the location and construction of a house; the effect of ground-air and ground-moisture upon health, and the consequent necessity for thorough soil drainage; house drains, their defects, how to discover and remedy them; ventilation, heating, and personal habits.

This is the first college in the country to make "hygiene" a part of the regular curriculum. When will the authorities of our medical colleges, in this, the *alma mater* of American medicine, commence to appreciate the importance of sanitary science, and place its teaching side by side with physiology and anatomy?

NOTES AND COMMENTS.

A Case of Causalgia.

A woman sustained a fracture of the lower ends of the bones of the legs. After a perfect union, there was slight stiffness of the muscles on posterior surface of the leg. Some weeks later she began to experience an uncomfortable burning sensation in the sole of the foot after walking, which gradually increased in severity until it assumed a very painful character. When Dr. Charles T. Poore, who reports the case in the *New York Med. Jour.*, February 3, 1883, saw her, she described the pain as follows: After walking a short distance, or letting her foot hang down with a boot on, the sole of the foot, at a point corresponding to the metatarso-phalangeal joints and a little behind them, began to burn; soon the skin became very sensitive, red, swollen, and the pain excruciating, so that she had to remove her boot; she had noticed that at times the skin had a glazed appearance. During the paroxysm the pain extended up on to the side of the foot, and then to the leg. When the pain was intense, she obtained relief by placing the foot in as hot water as could be borne. She had no pain when the foot was raised, even if she had a boot on. After an attack, the pain gradually diminished, and in an hour or so it disappeared. Electricity and iodine locally were useless. A Paquelin's cautery raised to a white heat was applied to the painful point on May 17th. The patient complained of but slight pain from the application, and was out in the afternoon. From this date until the 1st of June the foot was cauterized five times, with an almost entire relief from pain. She is now free from all

trouble, and goes about as well as ever. This disturbance in circulation was probably due to a traumatism of the posterior tibial nerve.

Pulsation of Spleen in Aortic Incompetence.

The *Medical Times and Gazette* says, it would appear that this sign of aortic incompetence has not been previously described. Attention has now been drawn to it by Dr. Gerhardt, in the *Zeits. für klin. Med.*, IV., S. 449, without any attempt being made to magnify the importance of the phenomenon. We are familiar with pulsation in the smallest vessels of many of the visible parts of the body in aortic incompetence, including the bed of the nails; and Quincke has shown how the two factors necessary for its production are, relaxation of the vascular walls, and sudden great variation in the blood-pressure, such as occurs in aortic regurgitation. In Gerhardt's three cases the spleen was large and the patients in high fever. The splenic tumor swelled during cardiac systole, expanding gradually, and diminished in size again during diastole. A dull double sound was audible over the tumor, apparently distinct from the cardiac murmurs, which could be made out at the upper part of the tumor. To the finger the pulsation had not the characters of an aneurism, but was of the nature of a soft swelling, very much as in pulsating jugulars. The sign appears to be not entirely without some prognostic value, inasmuch as it indicates a sound condition of the left ventricular walls, and compensation, as far as possible, of the valvular inadequacy.

Intestinal Obstruction Treated by Rectal Tube.

Dr. J. Foster Bush reports (*Boston Medical and Surgical Journal*, February 1, 1883), three cases of intestinal obstruction, all of which came on after indulgence in improper food, and were relieved by injections through a rectal tube. The tube was introduced for a length of twenty inches, and injections of water were made once and sometimes twice daily through it, but a second was never given till the patient had recovered from the bad effects of the first.

In the first case mentioned the only time the injections were suspended for any length of time was when pain and intestinal spasm had been created; and whenever this is done, or whenever we have fear that the intestinal structures have been weakened by inflammation or ulceration, of course the injections would be contra-indicated.

Distention from below is not a new method, and other means than fluids have been employed. Air, for instance, has been forced in by means of

a pump or bellows, or by chemical action, as by the injection of an alkaline followed by an acid solution. These last have only to be mentioned to be discarded, for they have not the soothing or relaxing properties of the water, which also exerts a force directly proportionate to the bulk employed, by reason of its compressibility and by its being regulated at will.

Blenorrhagic Pleurisy.

Several years ago Dr. Sée observed a case of gonorrhœal rheumatism, complicated by pleurisy. To his mind the pleurisy was evidently due to the venereal disease, since the two inflammations, arthritic and pleuritic, commenced at the same time and without any previous exposure on the part of the patient. Quite recently he saw another instance of this rare complication of gonorrhœa (*Journal de Médecine*, December, 1882). This was the case of a young man, twenty-five years of age, who had contracted a gonorrhœa some three months previously. He was suddenly taken with chills, followed by pains in his side, fever, and dyspnoea. Pressure upon the sides of the thorax induced the most acute pain. Upon his admission into the hospital, he showed evident signs of pleuritic effusion with extreme dyspnoea. He was not benefited by hypodermics of morphia. A hypodermic of nitrate of pilocarpine, however, gave an excellent result. Dr. Sée insists that the thoracic pain, and the general, instead of the local disorder, is sufficient to establish a diagnosis of true gonorrhœal pleurisy.

Digestion of Meat.

Dr. P. Hönigsberg has made a number of experiments to determine the digestibility of meat. His results, which seem to be reliable, contradict somewhat our views hitherto held in regard to this subject (*Wiener Med. Blätter*, 1882, 19 and 20). Raw, cooked and fried meat was digested artificially with gastric juice, prepared out of five grammes pepsin dissolved in 1,000 cbctm. acidulated water (1 p. c. hydrochloric acid). Syntonin was removed by neutralization, albumen by boiling, and hemi-albuminose by treatment with acetate of iron. The solution was decomposed with phosphor-wolfram acid, the nitrogen determined in the precipitate and pepton calculated. It was found that fried meat is most perfectly digested, raw less, and boiled still less.

Ergotine Suppositories.

M. Liebrecht, of Liège, has found that ergotine administered in this way is very rapidly absorbed,

its action is energetic, and it provokes no pain. With smaller doses than are usually employed in hypodermic injections, equal or even superior effects are obtained.

The following formula is serviceable:

R. Dialyzed ergotine,	1½ grams
Ol. theobromæ,	1½ grams
Vaseline,	½ gram, M.

For one suppository; three may be applied weekly. The uterine affections, in which injections and suppositories of ergotine are of benefit, are: Fibroids, menorrhagia, metrorrhagia after labor, at the period of the change of life, or when tumors are present; finally in chronic metritis and endometritis. For hypodermic injection, M. Liebrecht uses exclusively pure dialyzed ergotine.

The Stomach of an Idiot.

The *British Medical Journal* says that from the stomach of an idiotic girl, aged 10, who died recently, there was removed a mass of vegetable fibres, (straw, twigs, fragments of matting, thread, etc.) so interwoven and moulded as to make a cast of the stomach and duodenum. The stomach was 18 inches in length, and weighed 31 ounces. The case is interesting as showing how, in an individual of low nervous organization; obstruction of the stomach, by a gradually increasing mass, might for a long time be tolerated without any obvious symptoms of irritation. What next?

Tetanus in Typhoid Fever.

Dr. Morris Fussell, in the *Medical Times* for January 13, 1883, relates briefly two very interesting cases of tetanus complicating typhoid fever during the stage of convalescence, one of which terminated fatally. He failed to find any idiopathic cause for these occurrences, and suggests that they were probably traumatic in origin, the traumatism having been inflicted by the nozzle of a rectal syringe, by possibly abrading slightly the mucous membrane on the surface of a hemorrhoid.

Treatment of Gonorrhœa.

A rather large number of American, German, French, and English physicians have—as we see by reading through the many different foreign and domestic medical journals—of late been reporting very successful results in the treatment of gonorrhœa by the *yellow oleum santali*. We learn that the remedy invariably puts an end to the discharge within two days, but to prevent a relapse it has to be continued for two weeks longer. From 15 to 20 drops given three times daily is the usual dose, which may be administered on sugar or in gelatine capsules.

Infantile Ascites.

Professor Simpson exhibited to the Obstetrical Society of Edinburgh (*Medical Press*, January 17, 1883,) a case of a child which died immediately after birth from ascites of the peritoneum. There was fluid in the scrotum, showing a direct connection with the peritoneum.

SPECIAL REPORT.

* REPORT OF PROGRESS OF OTOLOGY, NO. 2.

Diseases of the Ear in Children.

(Continued from p. 222.)

Earaches in children are well-known to be often extremely severe and continuous, and it is not wonderful that the cries of the child, produced by them, should be loud and bitter, and that it should continue with slight intermission for hours till the little patient is completely prostrated and hoarse. How natural it is that with the exceedingly impressionable brain and spinal cord of a child, all these "nervous" symptoms produced by an exudative inflammation of the middle ear should be much more marked, and that in a child the confounding of the ear disease with a meningitis should really be very easy. The symptoms of the ear disease, such as great increase in the pulse and temperature, with frequent vomiting, constant stupor bordering on complete loss of consciousness, irrational talk and screaming, great restlessness with an anxious opening of the eyes, before which objects move, and the conditions of irritability increasing to twitching of the facial muscles and to convulsions of the limbs, all tend to lead one to expect rather an internal affection than an ear disease. Many years ago, Schwarz, of Fulda, so expressed himself in a decided manner, and Ludw. Meissner wrote, "The inflammation of the ear is certainly one of those diseases which is most frequently overlooked in young children, as they are unable to define the seat, the kind, and the severity of the pain." Most commonly it is mistaken for inflammation of the brain. Helfft compared the symptoms of inflammation of the inner ear in young children to those of genuine meningitis. Hauner expressed himself later in a similar way. Streckeisen in his "Bericht über den Kinderspital in Basel, 1864," says, "In the pneumonia of infants, convulsive symptoms showed themselves usually in the last three days (of life), and the explanation of these was found on dissection to be purulent inflammation of the tympanum and its meningitic connec-

tions. The most valuable contribution is that of Steiner. As it concerns older children, he expresses the opinion that the chief cause of brain symptoms in the so-called cerebral pneumonia is a simultaneous purulent inflammation of the ears, as he observed in sixteen children, aged from five to ten years, that with pneumonia of the apex, the brain symptoms (a comatose delirium) disappeared as by magic on the appearance of a discharge from the ear. As the chief symptoms, which continue in variable intensity till the appearance of the otorrhœa, Steiner enumerated "vomiting, somnolence, alternating with great restlessness, delirium, expressions of pain in the head, a dulled intellect, or complete loss of consciousness."

A distinguished American physician, the late Edward H. Clark, Professor of Materia Medica of Harvard University, Boston, published twenty years ago: "So important is a proper attention to the ears during and after the disease just referred to (exanthemata), that the physician who treats such cases and neglects to give this attention, cannot be said to perform his duty to his patient." See also paper on the same subject by D. L. Turnbull, Ohio.

In regard to the cause and prognosis of an acute otitis media, the great width of the Eustachian tube in children must be regarded as a very favorable circumstance. "In older children or in the intense forms of acute inflammation of the middle ear, the disease, as during scarlet fever with diphtheritis of the nose and pharynx, an early paracentesis of the drum-membrane is, without doubt, the best treatment; with good illumination, the operation is very easy, and can be performed with any long cataract or corneal paracentesis needle; if it is to be done on the posterior half of the drum-membrane, which lies most exposed, it should be remembered that this portion is sharply inclined, its lower part lying deeper and consequently farther from the operator than its upper part. After the operation, the pus should be evacuated as thoroughly as possible by Politzer's inflation, and the fluid absorbed by a pellet of absorbent, not syringed out of the meatus with warm water, or injections of one per cent. salt or soda solution.

With this disease, the affection of the nasal and pharyngeal mucous membrane should always be treated. It is more convenient and thorough to use the nasal douche of Theodore Weber, but with great care.

Never use plain water, but if nothing special is ordered, either a solution of salt or milk and

water. Always have the water lukewarm (77°-90° F.) Never have the reservoir higher above the nostril than $1\frac{1}{2}$ feet. Avoid swallowing, and breathe quietly through the mouth during the operation, and, with children, occasionally interrupt the current. Direct the stream backwards, never upwards. The atomizer for the nasopharynx is especially used for this purpose. If the mucus is viscid, and apt to form crusts, a solution of soda should be used; if decomposition of the secretions of the nose has taken place, a disinfectant, with potassii permanganate or with salicylic acid, added to a borax solution.

In regard to chronic aural catarrh, when children have reached the age of one or one and a half years, and utter no sounds such as ma-ma, pa-pa, and do not even begin to affix words or sounds to the things with which they are daily surrounded, accurate observation should be instituted to learn how far the power of hearing exists. Every teacher will allow that deaf children are particularly prone to become fickle and visionary. As has already been said, in children a great variation in the hearing and in the other symptoms is noticeable.

What the fingers do by closing the nostrils in the physiological experiment, is accomplished in the catarrhal child by the swelling of the mucous membrane and the collection of mucus in the nasal cavity. Frequent insufflations of air into the nostrils by means of a rubber bag (the dry nasal douche of Lucæ) are in such cases of very great value.

In sub-acute cases, they often speak of a knocking or hammering in the ear. The meatus, as it does not take part in the pathological process, is normal. The drum-membrane, just before the rupture takes place, shows a loosening of its epidermal layer, which produces a perfectly opaque and whitish-gray appearance. After attacks of pain, extravasation can often be seen on the surface of the drum-membrane. The outer surface of the membrane is not otherwise altered, except that some of the blood vessels which run along the manubrium, or radiate towards the periphery, become visible. This radiating injection occurs when there is a large collection of secretion in the tympanum, and makes itself apparent sometimes by very marked changes upon the surface of the drum-membrane, when grayish or yellowish vesicles or hernial sacs appear.

In children the membrane, even when the tympanum is filled with fluid secretions, is much less commonly bulged outwards in some of its parts. In a child, up to a certain age, the drum-mem-

brane is thicker and less transparent from the development of its surface layers.

During the course of catarrhal processes, there are produced various changes and irregularities in the color and the surface of the drum-membrane. Sometimes certain spots become opaque or otherwise discolored from circumscribed thickenings of the tissue.

To inspect the conditions of the tonsils, the mucous membrane, and the posterior walls of the pharynx, first depress the tongue with a spatula or finger. In the case of very small or intractable children, the opening of the mouth can be enforced by closing the nose. If the child can be persuaded to sound a loud "a," a better view can be obtained, from the raising of the palate which is thus produced. The inspection of the nasopharynx by rhinoscopy is only possible in exceptional cases in children under ten years of age, but a tactile examination is readily made with the finger, even by those whose fingers are short.

As we have already seen, the whole catarrhal process in the middle ear is, in the majority of cases, the result of the readily-occurring closure of the Eustachian tube, and we are justified in once more calling attention to the action of such a closure. We have already spoken of the very great advantages of the nasal douche. The inhalation of water, milk, or medicinal preparations from the hand is often necessary as a preparation for the nasal douche, but the same method is of undoubted value after washing out the nose, or in many cases, even without this latter procedure.

When there is a great deal of mucus, and the child does not understand how to blow the nose, air should be driven in forcibly from a syringe or from an air-bag, in order that a part of the obstructing secretion may be evacuated either into the pharynx or through the other nostril—a procedure that, in young children, is extremely useful as a preparation for the nasal douche.

In cases in which the nasal douche is, from any cause, contra-indicated, as, for instance, when one nostril is closed from malformation or granulations, or where it is desirable to apply medical solutions to the mucous membrane in small quantities or minutely divided, a finely perforated tube can be introduced for douching the pharynx, or an atomizing apparatus may be used; but if it is desired* that the finely-divided fluid shall reach far backwards, an instrument must be used, the tip of which ought to be a tube long enough to reach the naso-pharynx, of flexible metal, so as to bend and accommodate itself to the irregular surfaces of the turbinated bones.

For some cases of chronic nasal and naso-pharyngeal catarrh, the use of sal-ammoniac vapor in statu nascenti is very beneficial.

Inflammation of the palatine tonsils often keeps up a chronic inflammation of the pharynx, just as a foreign body would, producing mechanical irritation and disturbances of circulation; they also interfere with the movements of the palate, and by pressing its posterior surface upwards against the tubal orifice, narrow or even close those passages.

In children and young persons the removal of hypertrophied tonsils improves the condition of the ears and of the hearing, often in a marked degree, and is always favorable to the chronic pharyngeal and nasal catarrh. In children of families where there is an hereditary tendency to catarrhal deafness, enlarged tonsils should be early removed as a prophylactic measure, even when the ears are intact. After the operation children breathe much deeper, and consequently the chest becomes more fully developed, the blood richer, and the child, previously pale and without appetite, improves in its whole constitution. If the enlarged tonsil is only soft, some improvement can be expected from iodine in gargles, and from frequent paintings with the same, long continued. (A paste of equal parts of caustic lime and caustic soda will be found very valuable in reducing this condition of the tonsils in children without an operation.)

Fahnestock's tonsillotome works admirably for children with whom it is impossible to use a knife; the larger tonsils should always be first removed. Ice is an excellent styptic and antiphlogistic. In regard to the local treatment of the ear necessary in chronic catarrh, the air douche is above all else the most important agent.

It will also be understood, from what has preceded, that paracentesis of the drum-membrane is very often desirable for the rapid evacuation of fluid secretion; the operation is, however, absolutely necessary when, in spite of repeated air douches, the fluid in the tympanum does not disappear, or the improvement from the inflation continues to be merely temporary.

The advice necessary for the hygiene of children suffering from chronic aural catarrh will be understood from what has already been said on the etiology of the disease. To the bad air to which children are frequently exposed, in their living and sleeping rooms, and school-rooms, the physician, in fulfilling his duty in preventing disease, should have a watchful eye. The ear may be affected by pathological conditions of the body,

and especially of the circulatory system. Of course our therapeutic measures must often be directed to such general diseases.

Diseases of the Mastoid Region.—After incising a subperiosteal abscess, the bone may be found softened, roughened, or even with a fistula through it, and the best course then, is to remove the diseased spot immediately.

The cortical substance of the petrous bone is so thin in small children that a strong pressure with the knife is often sufficient to open the cavity; but it is much better to make a large opening into the antrum mastoideum by means of a sharp spoon, a gouge, or Luër's gouge-forceps. Of the 44 operations by Schwartze, 16 were in patients less than 15 years old.

Extensive necrosis of the petrous bone occurs rarely when we remember the frequency of the suppurations of the ear.

Diseases of the Inner Ear or Labyrinth.

The view that the nutrition and blood-currents of the membranous labyrinth is principally influenced by intercranial process, corresponds with the anatomical experience of Schwartze.

The disease cerebro-spinal meningitis finds most of its victims among children, and is the cause of innumerable cases of deaf-mutism. Unfortunately we have but few accurate reports of the appearances of the ear in such cases of deafness produced by cerebro-spinal meningitis.

And a still greater difficulty is presented in the differential diagnosis between acute meningitis and other intracranial processes on the one hand, and purulent processes within the labyrinth on the other hand, as a very rapid diminution or complete loss of hearing power is common in both varieties, and a large number of similar appearances are found in each.

Comparing the characteristics of the disease in question with the well-recognized symptoms of meningitis cerebro-spinalis epidemics resulting in deafness, the very great resemblance will be recognized by every unprejudiced mind.

Let us now return to the consideration of those disturbances of hearing which, from the absence of changes in the peripheral parts of the ear, or from reasons of probability, we regard as the results of anomalies in the nervous apparatus. Such anomalies may be frequently the reason why children, and especially those who are unusually slow in their development in all particulars, only begin to talk very late and make such slow progress in their speech. Not uncommonly parents and physicians think of the hearing only after a long time, and then the most superficial tests im-

mediately show it to be very much impaired. If the ear is carefully examined by an expert, the presence of changes in the tympanum, which may have been produced in early life, or which may be even congenital, cannot be denied with certainty; but there are cases where a congenital defect and arrest of development in the nervous or central apparatus may be diagnosed with the greatest probability.

Such are cases where the formation of the skull is peculiar, the intellectual development and power of walking are less than natural, and especially those where congenital anomalies and affections referable to the central nervous system, such as idiocy, epilepsy, deaf-mutism, exist in the family, particularly in the other children. In some of these families old syphilis is an important element, as it is very apt to be in cases of total or very extreme deafness. It should by no means be understood, however, that in the majority of these cases anything is to be gained by specific medication. More commonly the indication rather is to try the treatment for chronic tympanic catarrh, as already given, if any reason is found for it in the condition of the ear, nose, and pharynx, or in the gradual diminution of the hearing. More can be gained not infrequently in this way than was first expected. It may happen that, in addition to the congenital defect, catarrhal changes have occurred which still further reduce the hearing power, and, if an improvement or even the arrest of progress can be brought about in this, something has been gained. Only a properly-conducted treatment can, as a rule, show in how far the conditions in the tympanum are irremediable. The less the degree of hearing, and the more invariable it is, the less prospect is there of a result from such treatment.

In old nervous lesions any treatment is wholly useless; in recent ones it is advisable to try bleeding, derivatives, resorbents, and, later, electricity in one form or another, as sometimes the hearing power of itself improves up to a certain point, and an absolutely incurable process cannot be assumed at the very beginning.

Deaf-Mutism.—The same anatomical changes which at a later age simply cause total or great deafness, will, when they occur in the fœtus or young child, interfere with the development of speech: or, if the child has already learned to talk, cause it to lose its speech. In either case the child is a deaf-mute.

Among the diseases which most commonly produce total deafness, and therefore deaf-mutism, are acute otitis in scarlet fever, especially when

associated with diphtheria and epidemic cerebro-spinal meningitis.

Care should be taken not to consider deaf-mutism as an isolated symptom, wanting in all variations of degree. If with children who are only extremely and not totally deaf, conversation through the ear-trumpet had been used early, and if they had been obliged to talk in the same way into their own ears, the learning of articulate speech would have been much easier for them; or in the case of a deafness acquired later in life, the distinctness of utterance would have been retained. If treated like an adult, and spoken to distinctly and slowly into the ear, or better, through an ear-trumpet, and at the same time if shown the object referred to, they can be gradually brought to perceive and understand what is said, will take an interest in using the hearing, and will very soon begin to imitate what is said and to speak. If the exercises in speech were further aided by obliging the child to talk often through the ear-trumpet into its own ear, in order that it may perceive its own voice, it would gradually gain control over this and over its pronunciation. Such a course of instruction, properly and consecutively followed out, would result in the child remaining simply hard of hearing, but possessing a tolerably distinct articulation; in other words, deaf-mutism would be prevented.

It is also very desirable to practice the child in reading words from the lips and repeating what is said. V. Trölltsch can recall several children with aural suppuration, who had already been placed in deaf-mute asylums or were regarded as hopelessly deaf-mutes, in whom deafness was so much reduced that individual instruction—and in one case even attendance at a public school—was sufficient to give them a very fair education and pronunciation. Institutes exist in which the instruction of very deaf children is being undertaken in the proper method, and it is no longer necessary to send them to deaf-mute schools when means do not allow of their being instructed alone.*

In most of the cases of those who have already learned to talk, the loss of speech from deafness occurs in the fourth year, occasionally even up to the tenth year, and only in extremely rare cases up to the fourteenth year. Children who can already speak may lose this ability if they become deaf at any time up to the seventeenth year. Even in the eighth to the ninth year, the loss of hearing may make speech very imperfect.

*See Turnbull on Imperfect Hearing and teaching deaf children at home and in public day schools. J. B. Lippincott & Co., Philadelphia, 1881.

The speech always lacks the euphony which is only attained and regulated when the person can hear his own voice; it is somewhat hoarse and monotonous, and characterized by the peculiarity that the single syllables are not run together, but sharply separated; the voice is as a rule, too loud, rough and irregular, without modulation, but this can be much improved by teaching them Bell's method of visible speech. The regular use of the voice counteracts the tendency to the development of the respiratory disease to which deaf-mutes are particularly liable. It is well established that an unusually large number of these unfortunates die of tuberculosis between their fifteenth and thirtieth years. Meissner (l. c., p. 130) gives a table of 61 deaths of pupils who were or had been in the Leipzig asylum. In 59, the cause of death was fully established; and 30 of these died of consumption of the lungs, 4 of inflammation of the chest, 1 each of pharyngeal phthisis, phthisis, and hydrothorax.

Finally, it should be stated that an immediately direct hereditary tendency to deaf-mutism is less common than a family tendency, even when both parents are deaf-mutes.

NEWS AND MISCELLANY.

Co-Education of the Sexes.

The *Boston Medical and Surgical Journal* says that an affair unfortunate for the advocates of "co-education" in medicine has recently occurred at Kingston, Canada, which seems to have been precipitated by the women themselves. It seems that there have been mixed medical classes, and recently the ladies took offense at a remark made by the professor of physiology, and left the theatre in a body. Thereupon the male students petitioned the Faculty to dismiss the ladies, and even went so far as to threaten to leave the school themselves if their request were not complied with. A compromise was agreed upon: the ladies now attending classes will be permitted to finish their course, but no more will be allowed to enter, and for the future the medical school will be for men only.

Opium Smoking in the East.

Miss Bird, in her recent travels in the East, asserts from personal observation and inquiry that the use of opium no more frequently leads to the "opium habit" than the use of alcoholic beverages in England does to confirmed inebriety.

Another writer, in a recent issue of the *North China Herald*, maintains that the export of Indian opium to China is a great blessing to China, because it has been "steadily and certainly driving native opium out of the market, lessening its consumption, pushing the poppy farther and farther inland, and so has been wresting the land

from poppy cultivation and freeing an ever-increasing acreage for the growth of other crops. Indian opium, coming under the law of the 'survival of the fittest,' will force native opium to disappear, and with it the cultivation of the poppy, so that, instead of being an unmitigated curse, Indian opium is doing good work. It is the fierce antidote that kills the deadly poison; and, after having accomplished a double mission in India by supporting the introduction of Christian rule, and in China by freeing the soil from the incubus of a harmful growth, Indian opium will disappear before something nobler—will disappear before the moral regeneration of the millions of England and China."

A New Pile Clamp.

This is the new pile clamp, invented by Dr. P. E. Skillern, of this city. It is a self-retaining instrument, with a good strong spring, that readily holds and compresses the pile during the operation. The instrument is seven inches in length, the blade being two and a half inches long and one-half inch in breadth, with the approximating surfaces slightly indented to prevent slipping. Pressure on the handle opens the blades, and when applied, and the pressure removed, the pile is tightly grasped and the circulation completely cut off. The simplicity of the instrument, together with its easy application and cost, are the points that recommend it. It is made by Mr. Lentz.

Licenses to Practice in Illinois.

The Illinois State Board of Health has just given notice that after the current scholastic year license to practice medicine in Illinois will be granted to graduates of those schools only whose requirements include a preliminary examination on the essentials of a common school education. As but one medical school in the State conforms to this requirement, even on paper, at present, there is some stir in the various faculties as to ways and means for complying with the letter of the law.

Preservation of Butter.

The *American Journal of Pharmacy* notes that Dr. W. Hagemann has observed in *Chem. Ztg.*, 1882, No. 67, that cow butter contains 0.5 to 0.6 per cent. of milk-sugar, which under the influence of bacteria is transformed into lactic acid, and this liberates from the glycerides the acid, containing less carbon. It is obvious from this that summer-butter becomes rancid more rapidly and strongly than winter-butter, and that for the preservation of butter two methods may be adopted, viz., either the lower fat acids are removed by soda solution, as proposed by Adolf Mayer and Dr. Clausnitzer, or else the milk-sugar must be removed, or its decomposition prevented by suppressing the vegetation of the bacteria.

The Mortality of Large Cities.

According to the latest official returns, the mortality per 1,000 inhabitants in the cities named has been as follows: Calcutta, 32; Bombay, 26; Madras, 33; Paris, 27; Geneva, 17; Brussels, 22; Amsterdam, 26; Rotterdam, 29; The Hague, 32; Copenhagen, 20; Stockholm, 32; Christiania, 17; St. Petersburg, 36; Berlin, 23; Hamburg, 24; Dresden, 29; Breslau, 26; Munich, 27; Vienna, 27; Prague, 28; Buda-Pesth, 24; Trieste, 29; Rome, 21; Turin, 26; Venice, 32; New York, 22; Brooklyn, 21; Philadelphia, 21; and Baltimore, 32.

Brandy.

From the report of the American Consul at Rochelle, we learn some startling facts concerning the adulteration of brandy. In most cases the spirits sent to England for consumption appear to consist of beet or potato spirit, diluted to the proper strength, and flavored with genuine cognac, and probably not unfrequently with the addition of other flavoring materials, so as to produce such a taste as would pass for ordinary brandy, and then bottled and labelled so as to sell at the prices of genuine brands.

Sir James Paget's Toast.

Sir James Paget, in proposing the toast, "Prosperity of the British Medical Association," at the recent Jubilee, uttered the following beautiful sentiment: "Do not let our disputes be very noisy on the scientific side. Remember always that it is only through clear and undisturbed water that you can see what lies at the bottom. In storms of controversy there is nothing to be found but the billow that moves to mischief and the foam that disappears."

The Oil Palm.

The fruit of the African oil palm (*Elaeis Guineensis*) has many applications, and it would seem it might have many more. The natives use it as an article of food. The oil is applied to the skin as an unguent, and to relieve slight inflammations. An excellent soap is made from it, well-suited to delicate skins. A Philadelphia merchant, Mr. Edward S. Morris, has taken much pains in collecting and refining the palm oil, and his products are acquiring much popularity.

An English Tribute to Oliver Wendell Holmes.

London Punch thus felicitously rhymes on the resignation of Dr. Holmes from the chair of anatomy in Harvard:

Your health, dear "Autocrat!" All England owns
Your instrument's the lyre, and *not* "the Bones."
Yet hear our wishes—trust as they're not cold ones!
That, though you give up bones, you may make old ones.

The Pennsylvania Board of Health Bill.

Both the House and Senate bills to establish a Board of Health in this State have been killed for this session. We need not go into the reasons assigned for this discreditable fact. The effort was made to have the Board a mongrel one of eclectics, homeopaths, and such like "schools." This was

carried, and of course such a Board would probably be worse than none, so it was just as well that the bill was "indefinitely postponed."

Officers for the Massachusetts Dental Society for 1883.

President, Dr. F. Searle.

First Vice-President, Dr. A. B. Jewell.

Second Vice-President, Dr. D. M. Clapp.

Secretary, Dr. W. E. Page.

Treasurer, Dr. E. Page.

Librarian, Dr. R. R. Andrews.

Executive Committee, Drs. D. F. Whitten, F. E. Banfield, J. S. Hurlbut, J. F. Adams, Leon Rideout.

Officers of the Medical Society of Tennessee for 1883.

President, W. F. Glenn, M. D., Nashville.

Vice President, for Middle Tennessee: W. F. Clary, M. D., Unionville. For West Tennessee: E. Miles Willett, M. D., Memphis. For East Tennessee: G. A. Baxter, M. D., Chattanooga.

Secretary, C. C. Fite, M. D., Shelbyville.

Treasurer, R. Cheatham, M. D., Nashville.

Medical Society of the State of Pennsylvania.

The thirty-fourth annual session will commence at Norristown, Wednesday, May 9, 1883, at 10 a. m. All who desire to present papers at this session should send the title and time required for reading the same to Dr. J. O. Knipe, Chairman Committee on Programme, without delay.

W. B. ATKINSON, M. D., *Permanent Secretary*.

Items.

—A baby show, on the American plan, will be shortly held in Hamburg.

—The *Tiempo*, of Valencia, notes the birth of an infant with a beard and a full set of teeth.

—At Vienna and St. Petersburg, Physicians' Mutual Aid Societies have at length been organized.

—During the past year there were 300 persons killed and 1,000 injured in the anthracite coal mines.

—The newspapers say that Montreal exports to the United States about 150 subjects for dissection every winter.

—New York has just made the discovery that Central Park, from a carelessness about drainage, is a source of malaria and ill-health to the houses round about.

—The authorities at Berlin are discussing the propriety of prohibiting the importation of American pork, which is said to be largely infected with trichinae.

—A woman lay three days in a trance at Big Rapids, Mich. On recovering she believed that she had died and come to life as another person. This delusion cannot be dispelled, though in other respects she is sane.

—A Kentucky mule deliberately put its head through a crack in a post-and-rail fence, and stayed there until it choked itself to death. Such

instances of suicide are not rare among horses and some other of the lower animals.

—A California man feeds his family on raw fruit and coarse meal, to his great satisfaction; but when he told an audience of poor men how cheap and wholesome such a diet was, they got angry, and drove him out of the hall.

—The Chicago College of Physicians has been sued by a student who was promised a graduate's diploma at the end of one year's study. The faculty decline to keep the agreement, which was made, they say, by an individual teacher.

—One physician at Urbana, Ohio, said that another had killed a smallpox patient by mistaking the disease for measles. The retort was that the first accuser had caused a death by something worse than a blunder. Suits for damages are in progress.

—Massachusetts has an expensive and efficient State Health Board, with headquarters in the State House. But this did not prevent the Legislature from sitting in a room whose air was pumped in over a sewer, and whose ventilator was boarded up some time ago.

—The London *Engineer*, discussing the inability of man to fly, notes his weakness in physical strength as compared with fowls, and says no flying machine will ever be successful until so constructed that each pound of machine will develop as much energy as each pound of bird.

—In 1881 there were examined in the Municipal Laboratory, Paris, 3,001 samples of wine, of which 271 were found to be good, 991 passable, and 1,731 bad. In the first five months of 1882, 1,869 samples were analyzed, of which 372 were good, 683 passable, and 814 bad—145 of the latter being very injurious.

—A London dentist has invented a lamp for illuminating the cavity of the mouth during dental operations. It is of incandescent carbon, fitted into a vulcanite cup, covered for safety with a glass shade. The lamp is said to give a brilliant light just where it is needed, without producing heat, and the inventor freely offers its advantages to his fellow dentists.

—One of the New York city members in the Legislature at Albany has introduced in the Assembly a bill allowing everybody in the State to practice medicine. His name is Quinn, and, according to the terms of his bill, any man who has sense enough to come in out of the rain may be called on to attend a dying man, no matter whether he be ill of small-pox or a spavin on his leg.

—A man named Stewart has been arrested in Troy, New York, for the alleged murder of a woman. The statement in the papers is that a photograph of the dead woman's eyes disclosed upon the retina a picture of Stewart holding a chair over her head and just in the act of striking her. The matter has been brought to the attention of the Grand Jury. It is as well to add that this sort of evidence is illusive and probably fraudulent—unless the whole story is a hoax.

—Professor Sumner delivered a very incisive lecture in Brooklyn a week or two ago on some of the errors of social reformers. Its substance was

an elaboration of the theory recently put forth, that the death and decay of the drunkards and the vicious were an illustration of the natural law of selection and the survival of the fittest, by which the human race was being improved, and that any interference therewith to preserve them was a contravention of the law of nature.

—The fatalities of the foot-ball ground recur with remarkable regularity. Some of these deaths result from accidents on the field, but more are caused by injury to the constitutions of boys who are physically unfitted for such rough sport. In view of this fact the London *Lancet* makes the suggestion that "no member of a club be allowed to engage in club matches unless free from heart or other organic diseases." This rule might be applied to other athletic games with manifest benefit.

—If the United States Congress desires to do something for the benefit of the country at large, it might well follow the example set by the French Minister of Agriculture, who has placed \$10,000 at the disposal of M. Pasteur, to continue his investigation of contagious diseases of animals. Does Congress know how much money the Department of Agriculture of this country has saved through such investigations already made with entirely inadequate means? When the money value of such investigations becomes known, \$10,000 will seem like a very small amount to be annually appropriated to this one purpose.

OBITUARY NOTICES.

PROFESSOR BENJAMIN H. RAND, M. D.

Professor Benjamin Howard Rand, a well-known physician and scientist, whose death on Wednesday, at his residence on Summer street above Sixteenth, was announced yesterday, was 56 years of age, and was born in this city. He graduated from the Jefferson Medical College in 1848, and two years later was elected Professor of Chemistry of the Franklin Institute. From 1852 to 1864 he was Secretary of the Academy of Natural Sciences. He accepted the Chair of Chemistry in Jefferson Medical College in 1864, from which ill health forced him to retire in 1877. He was elected a Fellow of the Philadelphia College of Physicians in 1853, and a member of the American Philosophical Society in 1868, and was also a member of the American Medical Association. He was the author of several elementary works on chemistry.

DR. R. A. CROCKETT.

Dr. R. A. Crockett, a popular and respected member of society and of his profession, and an old subscriber and regular reader of the *Reporter*, died at his home in Williamson county, Tennessee, of hemiplegia, on January 31.

MARRIAGE.

WINTERROWD—HOLLAND.—At the Moravian church, in Hope, Indiana, February 15, 1883, by the Rev. F. R. Holland, the bride's father, assisted by the Rev. E. J. Regennas, N. S. Winterrowd, M. D., and Miss Jeanne E. Holland, all of Hope.

J. C. Baker & Co.'s Cod-Liver Oil.

Absolute Purity and Freshness

Secured by Specifying our Brand.

Prepared on the Halten Islands, Norway, with great care, from the finest selected livers of net-taken Cod Fish, at a season of the year when they are in their highest condition. Prize Medal, Paris, 1878; Berlin, 1880.

BAKER'S EMULSION,

With Hypophosphites of Lime and Soda, containing fifty per cent. pure oil, is a perfect and potent preparation.

We employ Baker's Cod-Liver Oil in preference to all others. The pure oil is palatable and digestible, and the Emulsion is well nigh delightful.

**THE PHYSICIAN'S
 CLINICAL RECORD AND CASE BOOK.**

FOR 100 PATIENTS.

Neatly Bound in Cloth, with Pocket and Stencil Plate, Price \$1.00.

This very convenient little book, adapted to be carried in the pocket, gives, in the briefest and neatest arrangement, the best forms of preserving the records of cases. A brass Stencil Plate accompanies each book, for rapidly sketching an outline of the body, in which may be marked, by shading, the seat of effusions, etc., or the size and position of organs, tumors, etc.

Several pages of prefatory matter are given, presenting in the most succinct form a number of memoranda to refresh the memory of the practitioner, as: 1. Memoranda in Examining Patients; 2. Symptoms of Poisoning, etc.; 3. The Urine in Disease. Ruled Temperature Charts are added.

COMMUNICATIONS.

BOUGIES, SUPPOSITORIES, ETC., OF GELATINE, FOR LOCAL MEDICATION.

[A paper read before the Medical Society of the State of New York, February 7, 1883.]

BY ROBERT NEWMAN, M. D.,
Of New York.

Surgeon to the Northwestern Dispensary, Permanent
Member New York State Medical Society, Honorary
Member Ulster County Medical Society, etc., etc.

For a long time the medical profession was in want of a convenient mass for the manufacture of medicated bougies and other forms for local applications to the mucous linings. Uterine pencils were used and recommended by Simpson, of Edinburgh, about twenty years ago. I followed his suggestions, but could not find a preparation to suit the indications; and all my experiments, with the assistance of chemists, failed. Urethral bougies I considered a necessity, and after many failures with different materials, forms, and compositions, could only use cocoa-butter compressed in a form as a vehicle for this medication. In the year 1869, I often ordered and used iodoform bougies, with considerable benefit to my patients. Soon after, a decided improvement was imported from Paris, as the "*Porte Remede Reymal*," a gelatine bougie medicated in various ways. But even this article was not practical, as it changed with the temperature, was too flexible, and even melted in hot weather, whereas in cold weather it was brittle and broke to pieces. As a rule it was too hard and stiff, irritating thereby the mucous lining, and even causing an inflammation. Another objection was the price, which for many patients

was too high. So this article fell into disuse by degrees, and now is almost wholly discarded.

Next, American industry produced different articles in imitation, of doubtful merit. It seems the difficulty was to find a combination with the gelatine, which remained sufficiently soft and flexible, without being affected by the change of temperature, and which mass would easily incorporate the remedial agent in a state of solution.

At last the article has been perfected by Dr. Charles L. Mitchell, of Ninth and Race streets, Philadelphia, and I greeted with pleasure about two years ago his soluble gelatine preparations, which I have used since with entire satisfaction. It gives me pleasure to exhibit to the society some samples of Mitchell's Soluble Medicated Gelatin Preparations, among which you will find: nasal, prostatic and urethral bougies, rectal suppositories, intra-uterine pencils, hollow vaginal suppositories, etc.

The latter have an especial merit—they are hollow and have the shape and elasticity of the finger of a kid glove. The cavity is filled with absorbent cotton, which acts as a tampon, keeping the medicated part in close contact with the mucous lining. The soluble part, after having done its work, is absorbed by the cotton, which prevents leakage and thereby promotes cleanliness.

The pressure exercised by these suppositories also produces an absorbent action on the indurated tissues, and has rendered me good service in removing indurations left after pelvic cellulitis.

Your especial attention to-day is, however, called to the urethral bougies, of which I here present a variety of samples, which are perfection,

and excel all similar preparations in the following points:

1. The bougies are elegantly put up, have a neat, clean appearance, and are always uniform.

2. The medicinal remedies are equally distributed and divided, being held in *solution*.

3. The bougies are soft, elastic, flexible, never break, and at the same time are substantial and stiff enough for an easy introduction.

4. After introduction, and in contact with the walls of the urethra, the mass dissolves readily and exerts an even and prolonged local action.

5. These bougies are not affected by change of the temperature, and remain uniform in any climate, neither do they change or melt in the hand.

6. Time will not affect the article. I have here some bougies which have been shown as samples, and for over two years have been lying around in my office, loose, unprotected, have received very rough handling, and nevertheless are now as good as new, having preserved all their good qualities.

Directions for the Use of the Bougies.

The best, in fact the only reasonable time for their introduction, is when the patient is at rest and in bed. Hence, bed-time is the most appropriate season. The patient lies in bed on his back, the bougie is slightly oiled, or moistened in warm water. I prefer the latter method, because then the medication comes in *direct* contact with the mucous membrane, and the mass dissolves more readily, whereas oil rather retards both results. Then the bougie is introduced into the urethra in the same manner as a Nelaton's flexible catheter—this movement must be done rapidly, but if an impediment is encountered a slight rotation, or a little withdrawal, is necessary, and another effort of introduction will then be successful. The latter end of the bougie should be pushed a little beyond the meatus, which is then held closed with one hand, the lips pressed together and secured by any kind of adhesive strips. Sometimes a small piece of cotton over the meatus, beneath the plaster, will answer still better, because the cotton (non-absorbent) will prevent the plaster from becoming moist and loosening its hold. A good way of securing this plaster more firmly, is to insert each end in the furrow between the glans and prepuce, and then sliding the prepuce upwards, using it as a kind of bandage to the plaster. The penis must be kept up, resting on the abdomen; its hanging down must be prevented, because it may irritate and thereby cause an erection, and also the running

out of the dissolved bougie. Both indications are fulfilled by applying a T bandage. If there is, during the night, a desire for micturating, the plaster can be moistened, loosened, and any remaining fluid let out. In some cases it is sufficient to leave the bougie in the urethra one hour, whereas in most cases it is better to let it remain the whole night. There are some cases cured by a single bougie, but the rule is that 10 to 12 nights medication are needed to cure an urethritis, and some patients use considerably more.

If it is desirable to limit the treatment to a certain portion of the urethra, a short bougie, or any part thereof, may be introduced through a tube and by a plug pushed to the place selected.

It is bad practice to introduce a bougie at the physician's office and let the patient walk about his business, as some of my young friends have done. It is a wonder if such careless experiments are not followed by severe inflammation of bladder, prostate or epididymis.

Indications for the Use of Urethral Bougies.

For a thorough understanding of this question it is best to begin to learn when medicated bougies should *not* be used. One rule will serve as a guide. Never use a bougie when its introduction causes pain. That means, no local applications should be used when the acute inflammation is at its height. In this stage any handling of the parts, or even the injection of a few drops of pure water, hot or cold, will cause severe pain, and cannot be tolerated.

The bougies can be used in all chronic cases in the third stage of urethritis, and they may also arrest the disease in its initial stage. When an uneasiness, even a slight soreness, is felt in the urethra, frequent micturition, and a slight watery discharge appears, sedative medicated bougies may arrest the progress of and abort the disease.

In chronic cases we use astringents, either alone or in combination with sedatives, antiseptics, or absorbents. Any particular remedy, combination, or formula, I will not recommend. Each practitioner must select these himself, according to general principles of practice, as indicated in each individual case. Standing formulæ and general routine degrade the practice of medicine to a trade. The art of the physician is to select the correct remedy, and graduate the dose to each case as it requires it.

I have used these gelatine urethral bougies in many cases for the last two years, with better success than any other bougie, and with more benefit to my patients than injections.

A few cases in brief will illustrate the use of these bougies.

Case 1. Acute Urethritis.

January 3, 1881. S. M. had a discharge from the urethra for two weeks, which commenced eight days after connection. He had no pain at first, but after using injections the inflammation has increased, so that at present he has very painful micturitions and erections.

January 4. A Mitchell gelatine bougie, containing two grains of extract of hyoscyamus and half a grain of extract of belladonna, was introduced in the urethra at bed-time. During the night the mass was dissolved and ran out.

January 5. He feels easier. In the evening a bougie, medicated with half a grain of sulphocarbonate of zinc, was introduced, and held there by a strip of plaster. It was tolerated the whole night. Discharge is rather increased, and soreness remains.

January 6, 7, and 8. Each evening a bougie was used, medicated with sulphocarbonate of zinc, after which the urethra felt easier.

From January 10 until 15, four more bougies were used, each time improving the patient, until he was well on January 17.

Eight bougies in all had been used to complete a cure during twelve days.

Case 2. Urethritis.

S. J. C., a merchant from the northern part of this State, contracted a urethritis while sojourning in New York.

September 28, 1881, came to my office and complained of a discharge from the urethra, which was accompanied by the usual irritations and pains of a gonorrhœa in the first stage. The patient was of middle age, had had this disease several times before, and the symptoms were not very severe. Treatment was commenced at once with gelatine bougies, formula No. 18, each containing half a grain of sulphate of zinc and one grain of extract of belladonna. For seven successive evenings I went to his hotel, and introduced each time a long bougie, filling up the whole urethra. The improvement was almost immediate, and on the fourth day he felt so well that he could not stand the temptation, and had sexual intercourse again. Even this indiscretion did not hurt him; the bougies were continued every night, and on the eighth day he was well and left for home.

Two months afterwards I saw him again, when he told me that he had been cured perfectly, and remained well.

Case 3. Gleet.

Mr. H. L., æt. 45 years, single, New York. Has done all kinds of extravagancies, had gonorrhœa

often, and has been suffering now for 7 years with a gleet, which off and on assumes the acute stage with purulent discharge.

September 26, 1881. Applied for treatment during one of his acute attacks. Had a thick purulent discharge from the urethra, frequent micturition, with pain and soreness toward the neck of the bladder and over the pubes. A particularly painful spot was found in the urethra, $4\frac{1}{4}$ inches from the meatus. Long gelatine bougies were ordered, each medicated with one quarter grain of chloride of zinc and one grain of extract of belladonna, formula No. 25. Every evening one bougie was introduced and left in the urethra over night. This treatment was continued with benefit, but at times exacerbations occurred. Patient needed for a cure two boxes of the bougies, which is more than the average, and this was due to the unusually stubborn, chronic state of his case.

Case 4. Gleet.

Dr. C. F., æt. 25 years, single. Had his first gonorrhœa six months ago, never was entirely cured, so that at present he has a gleety discharge and a desire to pass water frequently.

September 28, 1881. Treatment was commenced with gelatine bougies, each containing one grain of sulphate of zinc and one grain of extract of belladonna. Every other night one bougie was used. It was nearly a month before patient reported cured, during which time 12 bougies had been used.

Case 5. Gleet.

Mr. T. R. had been under my care for several venereal diseases, and left in good health for Chicago. During five years in Chicago, had been ailing with gleet and other discharges and emissions.

October, 1882. Came back to New York and placed himself under treatment for the above ailments.

October 22. At bed-time one bougie was inserted in his urethra, medicated with chloride of zinc and extract of belladonna. This bougie caused him some pain during the night, and the discharge was increased and became purulent the next day, October 23; but on the following day, October 24, all these symptoms had disappeared, and no traces were left of any disease. The patient was really cured with only one bougie. It seems that this application acted as a stimulant to the mucous lining, by which a healthy action was induced. Two weeks afterwards the patient was examined with the endoscope, and the whole urethra found healthy.

Case 6. Granular Urethritis, Prostatitis.

W. M., æt. 60 years, has been ailing for years with cystitis, urethritis, and prostatitis.

October, 1882. Has an irritation of rectum, a fullness of bladder, a desire to void water, must always pass water more frequently than when in health, particularly during the night, and feels more irritable in the bladder and penis in the morning; has a burning pain in urethra, and a soreness over the pubes.

Prostrate gland is enlarged, painful to touch, bleeds easily if any instrument passes over its interior lining. The endoscopic examination reveals a granular urethritis, a congested, red, mucous lining of the urethra, full of little granulations, denuded mucous membrane of a strawberry appearance, radiating lines with red and white points, with a white lustre over it.

The treatment consisted of local applications to granulated points through the endoscope; washing out the bladder; rest as much as possible.

October 21. Mitchell's urethral bougies, long, each containing two grains extract hyoscyam. and half a grain extract belladonna, were introduced into the urethra every other night. They acted well, and remained *in situ* the whole night.

On the alternate night a prostatic bougie, medicated with iodoform, was inserted through a tube, so that the medication was in contact with the prostate itself. The treatment was continued with short intervals for four weeks, when the patient was so much benefited that he left for home. An entire cure of the prostatic trouble is not claimed in this case.

Case 7. Urethretis Traumatica.

A. J., æt. 41, had retention of urine, and tried to pass a catheter himself, in order to relieve his bladder. His manipulations were such that he caused a violent urethritis.

September 28, 1882. He came under observation with a swollen penis, a sensitive urethra discharging abundantly muco-purulent matter. He had burning pain in the urethra, with frequent micturition, which was increased during the night. He was ordered gelatine bougies, one to be inserted into his urethra every night, each being medicated with extract of belladonna and sulphate of zinc. Only the first bougie smarted a little, the second did not hurt any more, and after the fourth he felt better. Eight bougies cured this case.

Case 8. Urethritis.

January 3, 1883. Frank C., æt. 24, contracted gonorrhœa twelve days ago; five days after connection he had a discharge from the penis. Yes-

terday (January 2) introduced bougie with zinc medication. This morning there was less discharge, but more pain in making water. It took two hours before the gelatine mass was dissolved. Discharge from penis was purulent.

January 4. Less pain; slight burning on passing water; discharge was less as compared with yesterday.

January 5. No pain on passing water; discharge very slight; no pain on passing bougie.

January 6. Patient appears to be well, and was discharged.

This acute case was cured with three bougies.

The last case is reported by Dr. McGillicuddy, who kindly observed a series of cases treated at the hospital of the work-house. The patients are all prisoners, who are kept under observation and control. The results, therefore, must be more reliable than in private practice.

These cases are not ready for tabular statistics, so as to be incorporated in this paper, but will be reported hereafter.

SCIATICA OF LONG STANDING CURED BY NERVE-STRETCHING.

BY DRs. JOHNSON AND WRIGHT,
Of Olney, Illinois.

Mr. C., aged 40, U. S. laborer. Family history good; has never had severe illness. He was firing at brick kiln for several days previous to the first attack of present illness. After firing for twenty-four consecutive hours, he was attacked, September 24, 1874, by a pain in right popliteal space, which continued, with varying degrees of severity, for five or six days, when he was suddenly prostrated by a lancinating pain in lower third of right thigh. Nausea soon followed. He was unable to move his right lower extremity for several hours.

This pain continued in a remittent form, attended by tingling in outer side of right leg, until December, 1874, at which time it became much less severe. During the winter of 1874-75 he was able to walk but little. He could sit in a chair without much pain, but attempts at locomotion always caused pain. During this winter his general health was fairly good.

From March to September, 1875, his appetite was poor, his bowels torpid, and his bodily forces considerably reduced. During all of this summer he had severe pain along course of sciatic nerve, and a feeling of stiffness and formication in right leg. During the fall of '75 and the following winter, his condition improved to such an ex-

tent that locomotion was tolerable, and he did some work.

In the spring of 1876 the pain became suddenly very severe in right hip—a catch. He was confined to his bed for two weeks, during which time he was unable to move his right leg without provoking a severe paroxysm of pain.

In June he had a relapse, and was confined to his bed most of the summer, his general health being much broken. Previous to this time his hygienic surroundings were fairly good. He received constitutional and local treatment, at times electricity, and morph. sulph. subcutaneously for forty successive days. He was worse during the winter of 1876-77 than during the corresponding periods of previous years. He was confined to his bed most of the summer of '77, and his sleep was much broken, and attempts at locomotion excited lancinating pain.

In summer he moved about on crutches, but his health was bad, and his pain was often severe, attended by a feeling of chill in lumbar region which would trace along spine to head. For 30 days in the spring of 1879 he was treated by inserting insulated needles deeply into thigh along course of nerve, and attaching the electrodes to them, and by the application of irritants to thigh. This treatment gave temporary relief. During the next two years his condition varied, he being unable to walk except on crutches. The pain would commence at an uncertain point in right hip, and extend along the course of the nerve down the posterior part of the thigh, through the popliteal space, under the fibula, behind the outer malleolus on to the dorsum of foot; again it would fly from one part of the limb to a distant one. During the two years preceding this date (fall of 1881), his hygienic surroundings were bad. He came into our professional care in August, 1881. We found him well nourished, weight 140, height 5 feet 10 inches, skin clear, thin, pale, facial expression indicative of pain. Tongue furred, appetite capricious, bowels irregular—often constipated. His sleep was much disturbed, and he was not refreshed by it. He was unable to stand erect, and he could not walk without the aid of crutches. Pressure just behind the trochanter caused pain, and there were several sensitive points on thigh and leg. He complained of pain about hip, thigh and leg, which was sometimes sharp, sometimes aching, often only a prolonged tingling. We gave him citrate of iron in sherry wine and, *cas. sagr.*, and *strychnia sulph.*, with morph. sulph. at night. We used deep injection into region of nerve of *spts. chloroform*. Gener-

ally the chloroform was injected into but one place at a sitting, the dose being 20, 30, or 60 minims according to amount of pain under which he was suffering. This treatment was decidedly beneficial, but not permanent. We also injected sulph. ether, but the relief was less pronounced.

On the 24th of November, 1881, we anæsthetized our patient, and applied the actual cautery to several points over the course of the right sciatic nerve. The white-hot iron was allowed to remain in contact with the skin only long enough to destroy it, and the scars were painted with strong carbolic acid. The cautery was applied in this manner again in January and in March, 1882. The pain from the burns was inconsiderable. Each application brought relief from the old pain. After the third he suffered no more in the right limb, a permanent cure being thereby affected.

During the months of April and May, 1882, he was able to move about his house on crutches without pain, but close confinement to the ill-ventilated, damp sick-chamber of his wife and daughter during these months impaired his general health, and he began to have pain along the left sciatic nerve. At first it was limited to the left hip; afterwards it extended to the lower part of corresponding thigh and outer part of left leg.

During all of this summer he received ferruginous and bitter tonics, laxatives, alteratives, and acids, as his condition seemed to need.

In June, 1882, we applied the actual cautery to this limb, but it did no good. In July we applied flying blisters with like results.

In October, 1882, we anæsthetized our patient for the fifth time, and having cut down upon the offending nerve just below its usual point of bifurcation in the lower third of the thigh, we seized it, having lifted it out of its bed, stretched it by pulling from above downward and below upward. Extensive, active inflammation soon followed the operation. The posterior portion of the thigh was much swollen for several days, causing much suffering. Pus burrowed into the upper part of the thigh, and formed in the calf, requiring several incisions to be made for its escape. The wounds were dressed with carbolized oil, and the limb with water dressings.

The inflammation has now, February 13, 1883, entirely abated, the wounds have healed, and our patient asserts he has not had any of the sciatic pain since we stretched the nerve, and that his limb is entirely free from pain. He can walk without pain in either hip, thigh, or leg, but the feebleness of his muscles requires him to use

crutches. He is gaining strength daily, and unless some untoward accident befalls him, he will soon walk without support. Verily, the operation has cured the man of his awful pain.

The following facts are worthy of special attention in this case:

1st. The chronicity—eight and a half years.

2d. The marked impairment of his general health.

3d. The number of well-informed physicians who treated him with as many different plans.

4th. The marked good following the use of the actual cautery.

5th. The cure by nerve stretching.

IODOFORM IN DIPHTHERIA.

BY DR. J. H. VOJE,
Of Fredonia, Wisconsin.

After reading the editorial on "Iodoform in Diphtheria" in your esteemed journal, I thought it my duty to report the results I have had with the remedy during a small epidemic of diphtheria here, which began the first part of November, 1882, and has not yet quite ended. Although I must state here that I did not in all cases use the iodoform exclusively, as the cases above four years of age also took the mixture recommended by Dr. H. Warren in the *MEDICAL AND SURGICAL REPORTER*, 1880, No. 7, yet are its beneficial effects nevertheless plainly shown. The iodoform was applied as directed by Dr. T. Benzon, in the *Wiener Med. Wochenschrift*, 35—'82, with the exception of the children below three years, in whom I used a powder blower, which I found more convenient. In those cases in which the nasal and post-nasal mucous membranes were implicated, these parts were also dusted with the powder-blower through the nostrils. In two cases also the steam atomizer was resorted to; in case 4 with lime-water, and in case 22 with lime-water and alcohol, equal parts, (Alcohol in Diphtheria, by Dr. Melsheimer, *MEDICAL AND SURGICAL REPORTER*, December 23, 1882,) in the latter case, whose larynx was involved, with the happiest result. I have not a very large number of cases to report, but they may serve, if added to others, in proving which is the best local remedy in diphtheria. In all twenty-four cases, nine males and fifteen females, between two and fifteen years of age, came to my notice and under my treatment. Four of these died, one boy aged seven years, and three girls, two five years old and one four years. Three of these cannot very well be counted, as one was dead when I came, and two were in articulo mortis, and died a few hours

after my call. The boy had laryngeal diphtheria when I saw him; this rapidly spread down into the bronchial tubes, and in two days he died, in spite of iodoform, steam atomizer, brandy, emetics, etc. I had not then read the report of Dr. Melsheimer, but I doubt if the alcohol would have saved him, as he had been sick five days, and the infection was too profound.

In the twenty cases left, iodoform was used with good results; in every case it brought the disease soon to a stay, and it would in a few days thin the membrane down so that it looked as if the parts had just been brushed with an argent. nitric solution. But I believe it did more, as I believe it prevented the membrane from forming in two cases, who had all the initial symptoms of the disease, and whose brothers and sisters were down with it. I applied the iodoform three times a day to the inflamed tonsils; no membrane formed, and by the fourth day they had no more fever. I found the iodoform to have the following advantages above other local remedies, viz: It is easy of application, and the children seldom object to it if once applied, as it causes no pain, but has a local anæsthetic effect, and has but little taste. It effectually stops the fœtor so disagreeable in bad cases, and brings diphtheritic ulcers to a rapidly healthy granulation; its effect on the temperature was marked, especially in the cases in which the iodoform was used alone. No case was sick longer than ten days. The disease was of a medium severe type. The pharynx, larynx, and nasal mucous membranes were in part of the cases involved; three cases have so far presented themselves with the characteristic paralysis as a sequela, aphonia, staggering walk, and one was also nearly blind for two weeks. In all cases the anæmia and prostration was very marked after the attack, however short.

Let me here state, as erysipelas has of late been brought into connection with diphtheria, that I had to treat during the time of the epidemic six cases of facial erysipelas of a very severe type, all in females between fifteen and sixty years of age; all recovered; only one case occurred in a house where there also was diphtheria—it was the mother.

OBSERVATIONS ON ECLAMPSIA.

BY H. L. W. BURRITT, M. D.,
Bridgeport, Conn.

In the *Compendium* for January, the question of Acceleration of Puerperal Convulsions (page 73) is stated to be an open one. I take it for granted

that by a large majority of the profession the following propositions are considered axioms:

1st. That bleeding *pro re nata*, as to quantity and according to constitution and strength, is indispensable, and its neglect almost criminal.

2d. That delivery the sooner the better is always the rule and not the exception, in all cases of eclampsia.

3d. That bleeding being premised, delivery will end the convulsions after half an hour.

4th. That delay is far more dangerous to the patient than the use of any means, manual or instrumental, to the end.

Hence I cannot see any force in the foreign authority or statements, "that delivery does not, as a rule, exert a favorable influence on puerperal convulsions," and that statistics, as given by Dr. F. Schauta, are unreliable, as his own exceptions—relief of pressure, restoration to the normal state, safety to the child, all deny his facts as given.

All experienced physicians have seen cases of convulsions in women seven to eight months pregnant, where even after bleeding the convulsions persisted until the os was forcibly dilated and the child turned and delivered, often with all the force of traction the attendant could use. I have seen thirteen of such cases without any bad result to the mother. In one case there were fourteen convulsions, six after bleeding to eighteen ounces—seven and a half months—fourth child, weight two pounds eight ounces—forcible dilatation—time, half an hour—only one spasm after loss of consciousness—child now five years old.

Turning is far preferable to the forceps, as there is no obstetrical instrument equal to, and no force so great, that can be used so safely, both in dilatation and extraction, as the *thinking* human hand; its power is sure, and it knows what it grasps, and it gives confidence to the operator. The experience of over a hundred cases justifies my opinion. Who ever heard of a case by a *regular* of injury to the mother where the hands were used alone? Is it not true that ergot carefully used, rupture of the bag of waters, and bleeding followed, by early and forcible extraction, have saved more mothers and children in eclampsia than any other method? Bleeding to save the brain, ergot as safety against the hemorrhage of chloroform, forcible extraction to relieve those terrible spasms, immediate relief where an hour's delay may be fatal, and bleeding, above all the anchor of safety—are not these *now* the established *rules* of the profession?

HOSPITAL REPORTS.

CLINICAL SERVICE OF THE PHILADELPHIA HOSPITAL, FEBRUARY 17, 1883.

DISEASES OF WOMEN.

Procidentia Uteri.

Dr. E. P. Bernardy exhibited a case of complete procidentia uteri, associated with cystocele, rectocele, and enterocele. The vagina was lax and flabby, and the uterus retro-flexed. When a pessary was introduced and the woman coughed, it was forced out. He deems this trouble to be generally due to sub-involution of the vagina after labor, when, on account of its relaxed and stretched condition, it fails to afford the normal support to the uterus. The only satisfactory means of treating complete procidentia, is operative, by resort to a modification of Sims' operation, by which the calibre of the vagina is reduced. Relief can be derived by packing the vagina with cotton soaked with a saturated solution of oak bark, tying the legs across a beam, and keeping the patient on her back for a week or two. In some slight cases relief can be obtained from the use of such strengthening injections as a saturated solution of alum and zinc, and occasionally tannic acid.

MEDICAL CLINIC.

Acute Rheumatism.

Dr. J. B. Walker presented a case of acute rheumatism which commenced as sub-acute. He laid great stress on the necessity of examining daily the heart in all cases of acute articular rheumatism, because, while *pericardial* trouble may direct attention to the heart, by causing pain, *endocardial* inflammation may run its course without offering any pain; and even when it does not, the joint suffering may be so great as to mask it. He believes in combining the salicylic acid and alkaline treatments; the former is curative to the rheumatism, while the latter controls the cardiac complications. There is no antagonism between the two treatments. He uses salicylate of sodium, twenty grains, and bicarbonate, acetate or citrate of sodium, or potassium, twenty grains, every alternate two hours. When joint pains have ceased, the salicylates are of no use, but the alkaline treatment should be continued as long as there are evidences of heart trouble. Large hot poultices over the heart are of vast service, but blisters will do no more than merely relieve pain, though a small (2x2) cantharidal blister may immediately precede the poultice. Avoid all exposure, and insist on absolute quiet. Salicin is tonic as well as anti-rheumatic, so that it may be substituted for the salicylate, when the patient is very weak. Tincture of chloride of iron is very beneficial in convalescence.

Pneumonia—Hydro-Thorax—Empyema—Pneumo-Thorax.

A very intemperate man, aged 37, was admitted nine months ago with delirium tremens, and in six days developed a pneumonia of lower lobe of left lung. When it got better, there was bulging of intercostal spaces over the normal heart area, and the apex-beat was felt under the right nipple.

There was also dullness and absence of respiratory murmur on left side, and at the lowest point, pitting on pressure, which is usually indicative of empyema. With the aid of a hypodermic syringe, purulent fluid was drawn off, when, on four different occasions, at intervals of two weeks, he was aspirated, and one-half pint of fluid removed each time. As it continued to form and threatened to burst, the gathering was punctured and a drainage tube inserted. A warfare with death now set in. He would pull down and recuperate, only to fall again; bed sores formed, and temperature ranged from 97° to 102°. The cavity was washed out with tepid water, and after a while the man got about. After some slight exertion and coughing, on January 6, blood was discharged from external wound; which again occurred on the 21st, and was checked by injections of a thirty-grain solution of nitrate of silver through a catheter. Salicylic acid and iodoform in glycerine, were injected each day for three days. At present he is receiving Basham's mixture and nux vomica, with stimulants, good diet, and friction to part. General amyloid degeneration is a not unusual sequel of prolonged purulent discharge, to prevent which, Dickinson recommends alkaline treatment, on the idea that amyloid disease is due to want of alkalinity of the blood. There is no such trouble here. He has now pneumo-thorax. When you place a coin over a cavity filled with air, and striking it with a key, listen through a stethoscope, you will have a sound like the ringing of silver bells. The patient is slowly improving.

Catarrhal Jaundice.

One of the most frequent causes is hepatic congestion or hepatic catarrh. Jaundice rarely results from suppression of the biliary secretion, but is caused by its absorption (after being secreted) into the blood. In acute yellow atrophy, where we have suppression, jaundice is seldom found. In this case, the bile has colored the patient's hair on account of its elimination in the sweat. To test for bile in urine, put a drop or two of nitric acid on a few drops of the suspected liquid on a saucer, and if bile be present there will be the characteristic play of colors, green, red, blue. When the hepatic catarrh has been relieved, phosphate of sodium in drachm doses, in warm water, will promote convalescence.

SURGICAL CLINIC.

After exhibiting a case of amputation at the lower third of the leg, which had been performed two weeks previously, and was doing well, Dr. Porter showed a case of

Balanitis,

caused by a tight prepuce preventing the exposure of the glans, and the consequent accumulation of smegma (from want of cleanliness), causing the inflammation. He is opposed to indiscriminate circumcision, believing that, in the majority of cases, nature will sufficiently retract a redundant prepuce at puberty; but where balanitis or any venereal disease exists, he advocates the operation. He proposes to slit up the prepuce on its dorsal surface with scissors, trimming off the edges and bringing skin and mucous membrane together with sutures. He does not like to use

phimosi forceps, because the skin is so slippery that with them you may only remove a ring of skin, even down near the base of the penis.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPEL.

Reported by W. H. Seelye, A. M., M. D.

(Continued from p. 152.)

Asthma.

GENTLEMEN: I show you again to-day, the same Patient who was the subject of our remarks the other day. You will remember that we then completed his physical examination. He slept well last night and says he is feeling better to-day. Yesterday afternoon he had a very violent paroxysm, from imprudence in eating. When we came into the ward, you noticed that he was lying quietly on his right side, but now, you see, he is disturbed and is suffering considerable discomfort.

I will now call your attention to some of the most important etiological features suggested by this case. You remember, I told you that his distress depended upon a spasmodic contraction of the muscles surrounding the bronchial tubes. The disease is therefore a neurosis. This is proved by its history. Hereditary affections such as this are often called hereditary neuroses. It is one of those nervous affections which sometimes take the place of other nervous disorders, and appear in different generations of the same family, in one form or another, or affect the same individual differently at different times. If we had not this hereditary peculiarity, as an evidence of its neurotic character, the striking feature of its sudden onset, and the speedy subsidence of the symptoms under the influence of controlling remedies, is sufficient to prove it. This is shown, moreover, by the fact that any unusual emotion, such as joy, laughter, grief, or any sudden nervous shock, will often bring on a paroxysm, and this always requires neurotic drugs to relieve it.

Etiology.—First, we will consider the exciting causes. We have in this disease an exceedingly exalted hyperæsthesia of the mucous membrane of the bronchial tubes, and the attack is excited by causes acting either directly or indirectly upon the mucous membrane, and producing either direct or reflex phenomena.

Asthmatics are sometimes made to suffer a paroxysm by inhaling certain odors, such as a rose or new mown hay, or by the emanations of certain animals, especially cats, or by taking certain kinds of food, or the action of some medicines. I have seen it brought on by breathing the dust of calomel; and ipecac is a very common exciting cause. All patients are not equally sensitive to the same thing, but each has his peculiar idiosyncrasies. An attack may be produced by various articles of diet, just as is the case in urticaria, a neurotic skin affection. And the same may be said of this, which Haverhill says of urticaria, viz, that "there is hardly any article of diet that will not produce it." Again, some are affected by certain kinds of air. One will be well in the country but not in the city. Another will be well on one side of the street but not on the other, or in

the front of the house and not in the rear. This is a peculiar fact, and one difficult to explain. You may have been treating a patient for a long time, and have found all medicines to fail, and are in despair, when some knowing neighbor will step in and tell your patient to move away, and on so doing he is immediately relieved, and you have lost your reputation. Again the attack is sometimes a reflex phenomenon, and may be due to the irritation of a loaded colon, and will be relieved by evacuating the bowels. Also indigestion or dyspepsia, certain articles of diet, or anything causing irritation anywhere along the gastrointestinal canal, may cause a reflex attack. The same effect may also follow from a current of air blowing on the surface of the skin. These are all indirect and reflex causes which act upon the nervous centres.

Diagnosis.—It would seem that one could hardly mistake the character of the affection in such a well-pronounced case; yet there are certain things to be carefully considered in making a definite diagnosis. All asthmas are not of nervous origin, or pure neuroses. In ordinary bronchial catarrh we may have considerable difficulty in breathing, and a certain amount of nervous difficulty causing labored respiration from bronchial spasm added to the other causes of interference. Again, a person may suffer from great difficulty in breathing after eating an unusually hearty meal, and so arouse the suspicion of its being asthma. But on auscultation you will fail to get the characteristic signs of asthma, and so you will be undeceived. So also you might be deceived by a dyspnoea due to cardiac disease. You see, therefore, that making a diagnosis requires some knowledge of the conditions which may simulate asthma. Remember that this affection is a neurosis, the onset of which may be gradual, but the distress slowly increases, and anti-spasmodic medicines are required for its relief. And it is frequently associated with a neurotic habit of body, or a neurotic hereditary history. By so doing, you will make no mistake in distinguishing this from bronchitis, heart disease, or obstructions high up in the trachea.

Prognosis.—This, I am sorry to say, is not very hopeful, unless relief is obtained by a change of climate. And circumstances often prevent this. This is an expression of the worst decision to which we can come. But it would not be right to say that there is not a great deal which may be done to relieve the patient, or that it is not in our power to partially control the disease. We must be cautious in these cases, and be in no haste to give a prognosis until we have tried the various means for relief.

Treatment.—What is the rational treatment of asthma? It differs from empirical treatment in that it involves the removal of the cause of the disease, while empirical treatment makes use of those remedies which experience has taught us will relieve the distress. You will see that there is a good deal in the way of rational treatment suggested by the pathology and the etiology. The disease is constitutional, and nervous in its origin. But we cannot easily change the patient's constitution, nor the character of his nervous system. Many of the direct causes can however be removed. If it be due to bad air, the patient may change his dwelling-place. If to certain

peculiar odors or emanations from animals, investigate and remove the cause. Then consider whether the asthma may not be due to reflex nervous action, from irritation on the integument or the mucous membranes of the body, and especially of the gastro-intestinal. Then investigate the diet and the manner of life carefully; and then remove these irritating causes, and give accurate suggestions as to the time and the things to be eaten, and thus you may give great relief. You will find that many asthmatic patients belong to a gouty race, and that they themselves, or their brothers, sisters, or parents, have suffered from gout or rheumatism; and knowing this, you can put them on the road to relief by using remedies appropriate for this disease.

From this man's history we learn that he has been an intemperate beer drinker, and he has had several attacks of rheumatism. Now in persons who are suffering from neuroses of any kind, the use of stimulants is, I am fully persuaded, a most serious and dangerous habit. I have frequently seen the neurotic tendency of constitution thus established, and this constitutional tendency is bound to be perpetuated in the progeny. These people should never be allowed to use stimulants, especially of the fermented kind. If they use any it should be distilled liquor, and it is sometimes necessary to administer this. But this man does not need any probably, for it aggravates the diseased condition of the nervous system. If he had abjured the use of alcohol earlier, he would probably have had no trouble of this sort. Where there is a gouty tendency, relief often comes from a modified diet, avoiding certain kinds of food against which the digestive powers rebel. This is especially important in gouty patients with asthma. They find difficulty in digesting the hydro-carbonaceous foods, such as fats, starch, and especially sugar. It is best therefore to withdraw these foods from them to a considerable extent, allowing them no sweets and but little starchy food, but allowing them all the animal food that they require. So in a few days the appetite and digestion will be improved, and relief experienced. Yesterday for dinner this patient had potatoes, and grapes, and other farinaceous vegetables, which underwent acid fermentation in his stomach, and as a result, within two hours after, he had an exceedingly violent attack of asthma. Proper directions in regard to his diet had been given him, but he did not follow them. He has had bread, beef tea, and milk, for both breakfast and dinner to-day, and as you see he has no severe asthma now.

A word as to the time of taking food. The principal amount of food for the day should be taken before three o'clock in the afternoon. It is found that the majority of attacks occur early in the day, between two and four o'clock in the morning, and this is particularly apt to be the case when a hearty meal has been taken in the evening before. So the supper should be light, and the breakfast and dinner hearty.

Now, a few words in regard to the means for immediate relief of the paroxysm. This embraces the use of anti-spasmodics, or medicines which depress nervous energy and relax spasm. So all the hypnotics are useful. Those most commonly recommended are belladonna, tobacco, lobelia,

stramonium, opium, chloroform, and ether. Most practitioners find belladonna, stramonium, and lobelia most effective; but I have been much pleased with the effect of opium, which I prefer. Chloroform is startling in its effects, but its action is only temporary, and the patient can not use it himself without danger, and he may form the chloroform habit. So it is better to make use of some of the other remedies taken internally. I will only give you here the principles of treatment, and not the details, which you can look up for yourselves. Fresh air and free ventilation are very important, and the application of dry cups is often beneficial, and was in this man's case yesterday. Many patients are relieved by the inhalation of the smoke of burning paper saturated with nitrate of potash. This "nitre paper" sometimes gives extraordinary relief. Others smoke cigarettes of stramonium leaves combined with the nitrate of potash. But all these remedies act only temporarily, and are useful for the relief of the paroxysm, and are largely empirical. The rational therapeutics is, as I have said, based on the fact that the disease is due to a neurotic habit of constitution, or is caused by reflex irritation.

MEDICAL SOCIETIES.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Analysis of Twenty-seven Operations for the Restoration of the Lacerated Cervix-Uteri, with Special Reference to the Effect on Sterility and Labor.

(Continued from page 235.)

CASE 4. Mrs. X. was sent to me by my friend Dr. Duffield, of McConnellsburg, Pa., in September, 1880. She was *æt.* 35, had had seven children and two abortions, the last one nine months before. She complained of pain in the lumbar region, a heavy, dragging pain in the pelvis, and very difficult and painful locomotion. These symptoms had been growing in severity for several years; she also had menorrhagia and leucorrhœa.

Touch.—Cervix large, soft, and lacerated bilaterally flush with the vagina. Mucous membrane engorged, everted, and eroded. Uterus retroverted, but mobile. The sound passed three and a half inches.

On February 27, 1881, I closed the rent, placing seven sutures. Union immediate. The result on the symptoms was all that could be desired. A letter a few days ago, in answer to one of inquiry from me, informed me that this lady is now pregnant.

Here are four cases in which pregnancy followed the operation, out of the class of eight in which impregnation had occurred within five years previous to the restoration of the cervix. And that there will be more, I feel sure, because a sufficient time has not yet elapsed since the operation was made, in some of my cases, to prove that sterility will continue.

That sterility does not result as a consequence of the operation, when the proper precautions are taken to secure immediate union and normal-sized

os, does not this analysis prove? That it will prevent a recurrence of abortion and cure sterility of recent date, Cases 1 and 2 give undoubted evidence. That it will fail to cure sterility of long standing, for reasons given in this paper, I am convinced from my own experience. Time, however, may prove that a small percentage of this class will also be benefited in this direction.

I have selected the following case from the class of thirteen in which sterility had existed more than five years prior to the operation, as strongly typical of the point I wish to illustrate, viz., that the longer the time which has elapsed between the occurrence of the injury and its repair (pregnancy being absent during this time), the greater and more permanent will be the changes in and about the uterus, which almost necessarily result in a continuance of the sterility after the cervix has been restored.

CASE 5. Mrs. M. R., *æt.* 39, consulted me in the fall of 1880. She had had six children, the last one thirteen years before. Her labors were all normal, so far as she knew, except the last. This was complicated by a malposition. The forceps were applied two hours before the delivery of the head, and great traction effort was necessary. The child was so injured by the forceps that it died on the third day after delivery. The patient was unable to be out of bed for nearly three months afterwards, and the bloody lochia continued during two months. She had suffered from menorrhagia ever since, and recently from metrorrhagia every two weeks, at times amounting to "almost a flooding." In the intervals between the hemorrhages, she had a constant and profuse mucous leucorrhœa. She complained of a deep-seated pain in the pelvis, "sawing" in character, with pain in the sacral and lumbar regions and across the shoulders. Coition could not be tolerated, because of the pain it induced and the hemorrhage which resulted.

Examination.—The perineum showed an old laceration of slight extent, and within an inch of the vaginal orifice the finger came upon a large mass of tissue which filled and distended the tube. It was hard and nodular around its border, but softer and rather friable in its centre; and it bled on the slightest touch. It gave me, at first, an impression of epithelioma, and I could readily detect that the cervix was bilaterally lacerated down to the vaginal attachment. The body of the uterus was hypertrophied, indurated, retroverted and slightly fixed from contraction of the broad ligaments. Through the speculum the cervix was seen to be lacerated, as the finger had indicated, and that the softer tissue, which occupied the space between the separated lips, was redundant mucous membrane, which seemed to have united from side to side, leaving a very small opening in the centre, corresponding to the external os. This tissue was dotted all over its surface with whitish spots—Nabothian cysts. The sound passed to a depth of minus four inches, and showed the uterine cavity to be rugous—vegetations of the endometrium. I now punctured the retention cysts, and found that the redundant tissue between the torn and separated lips was riddled with them. So much hemorrhage resulted from the scarification that, to check it, I was finally compelled to tampon the vagina. On the

next day I removed the tampon, and found the mucous membrane much reduced and less congested.

I treated this lady during a number of months for the purpose of relieving symptoms, and preparing the parts for an operation on the cervix. The hypertrophy and congestion of the mucous membrane of the cervix and uterine cavity were considerably reduced, the metrorrhagia and leucorrhœa diminished. The uterus became more mobile, and tenderness subsided; but the parenchyma of the cervix and body of the uterus remained sclerotic and unaltered in size.

On February 10, 1881, I closed the rent, after denuding the surfaces and dissecting away a large amount of cicatricial tissue from the sides and angles. I placed eleven silver sutures. Considerable difficulty was experienced in passing the needles through the dense and tough cervix, and I broke and bent several before I succeeded in placing all the stitches. The surfaces did not unite as readily in this instance as is desirable, but union was finally established by granulation, resulting in the formation of a good cervix.

This patient has been entirely relieved of the leucorrhœa and pain of which she complained, but she still has an occasional menorrhagia, and the body of the uterus remains large and hard, the sound entering three and a half inches. As was to be expected under these circumstances, she has remained sterile, but certainly not as a result of the operation.

Dr. Murphy further says: "I fear I shall never arrive at that perfection where it will be given me to appreciate why a laceration of the cervix, by being repaired, will probably prevent cancer of the womb."

I do not wish to discuss this subject here, as I am preparing a special paper upon it, but I would like to say that, if we believe that cancer may develop in consequence of the changes in the circulation and nutrition which necessarily follow when the cervix is torn, and it seems to me that one need not have arrived at perfection in the art of appreciation to believe that cancer might develop in a field such as was presented in Case 4 previous to the operation, then restoration of the organ ought to prevent cancer.

He also concludes, "That the character of the labor is unusually severe and protracted, and that, in a large percentage, laceration occurs a second time."

That this statement is too sweeping is abundantly proven by the cases I here record. I can believe, where pregnancy has happily followed the operation in a case of long standing, in which the cervix is sclerotic from connective-tissue hyperplasia, and cicatricial from non-occurrence of immediate union, that the first stage of labor might be tedious, and that relaceration might take place. But, suppose relaceration does not occur in some cases, is that sufficient reason to deprive the patient of the benefits which usually accrue from the operation, independent of pregnancy?

Not long ago I made the operation for the restoration of a lacerated perineum, which extended fully an inch and a half up the recto-vaginal septum, on the person of a lady fifty-one years of age. The laceration occurred twenty-six

years before, with a severe forceps labor. She had been debarred from the society of her friends, and made loathsome to her husband as well as to herself, all these best years of her life. In answer to my inquiry why she had not sought relief long before, she replied that she had done so, but that she had been advised to wait until after the menopause for fear that, in the event of another parturition, the parts would relacerate! Comment on such argument as that is unnecessary.

The comfort which this lady has enjoyed since the rectum and perineum have been restored, causes her to feel far from kindly towards the gentlemen who advised such conservatism.

I have recently delivered two ladies on whom the operation for lacerated perineum was made about three years ago, one by Dr. Goodell, and the other by myself. Relaceration did not occur in either.

Dr. Githens stated that on June 18, 1878, Dr. A. H. Smith had operated upon Mrs. M. for the restoration of a lacerated cervix; and on July 10 of the same year, had performed perineorrhaphy, both operations proving successful. On June 19, 1879, a year and a day after the first operation, I delivered her of a boy at full term, the labor being uncomplicated and easy, and no tear of either cervix or perineum occurring.

Dr. E. E. Montgomery remarked that as regards the question of sterility resulting as a consequence of the restoration of a lacerated cervix, he had been operating since 1879, and five of the patients he had operated upon have since become pregnant. The first patient upon whom he operated became pregnant lately, but aborted; as she had desired not to become pregnant, and was anxious that an abortion should occur, he believed that it had been artificially induced. Another patient operated upon in 1880 had been delivered in January, 1883, without accident. A patient operated upon in 1879 is now four months advanced in pregnancy; before the operation she had aborted at three months; this accident was apparently consequent on the existence of the laceration. Of these five cases, two were lacerations of long standing and three were recent.

Dr. Cleemann had operated upon one case of nine years' standing. During the first two years of that time she had two miscarriages, and then remained sterile for seven years. The operation was performed eleven months ago, and she is now two months advanced in pregnancy.

Dr. A. H. Smith had heard Dr. Baer's paper with pleasure. The general impression in this city is that sterility is a consequence of the injury, and a large proportion of the cases operated on by him have soon become pregnant after operation. The fear of the recurrence of the accident prevents pregnancy in many cases, as means are used to avoid that condition. Improved general health and local comfort are a result in a majority of these cases, even where pregnancy does not occur.

He would like to hear Dr. Baer's experience about the existence of obstinate nausea in pregnancies after operation upon long-standing cases accompanied with an enlarged and hardened condition of the cervix. It has been so with him. As regards the results of labor, there has been no tendency to relaceration in the same position. He

uses inhalations of chloroform and hot water douches in such cases, and does not rupture the membranes early; he also prevents the patient from bearing down, and by these means secures a slow and safe labor. He is sorry to hear that Dr. Baer has no confidence in the power of the operation to reduce the size of hyperplastic uteri. He has seen cases of the so-called sub-involute uterus, after the complete failure of local means, such as iodine, silver nitrate, etc., reduced one-third of its bulk by operating upon a laceration of the cervix. The rapidity with which the ultimate result of reduction in size is reached is in proportion to the time that has elapsed since the injury.

When the cervix is much hypertrophied, and ectropium exists, such a cervix as would formerly have been called cancerous, and would have been amputated, the stitches should be left in a long time. If they are removed too soon there is a proneness to gaping, a sort of ectropium or sprouting. This will not happen if the sutures are allowed to remain thirty to forty days.

Dr. Wm. Goodell regrets that he was too late to hear Dr. Baer's paper. With reference to the question of the influence of the operation in causing sterility, he thinks it does have such an influence. He has operated in one hundred and sixty-nine cases, and has only known of seven who have since become pregnant. There were probably more, as the cases have passed away from his knowledge, and he has never heard of them again, as he does not practice obstetrics outside of the Preston Retreat. In two of the seven cases a second operation was required, but it was slight. In one case not the slightest change occurred in the form of the os. As regards the effect of the operation in preventing cancer, he believes it fully, both from experience and from *a priori* reasoning. He has seen but two cases of epithelial cancer in women who have not borne children. In fact, his experience has been that the greater the number of children, the greater the liability to carcinomatous degeneration, and often the notch of a previous laceration is seen in the cancer. If carcinoma is, as we believe, a local disease at its beginning, what more probable cause could we have than such an irritating sore as a bad laceration of the cervix? In more than one case his principal reason for operating for the restoration of the cervix, has been an account of a history of cancer in the family.

Concerning the effect of the operation upon hyperplasia, he believes with both Dr. Smith and Dr. Baer. There is an element of passive congestion, the result of the irritation of the laceration, and when the cause is removed by the operation the effect passes away, and a great reduction in the size and weight of the uterus is secured. He believes that preliminary treatment in cases of enlargement with ectropium has a very great effect upon the results of the operation. Applications of iodine, glycerine, and tannin, and the use of the very hot douché, and cross-hatching of the enlarged Nabothian glands, have a softening and calming effect. In such cases, if the hard, gristly triangle in the apex of the wound be carefully excised, the tension on the stitches is slight. He generally removes the sutures in about nine days after the operation; in one case, in consequence of circumstances affecting convenience,

they were allowed to remain three weeks. When he can secure easy approximation and close coaptation, which is readily done by means of his guiding thread, perfect union is more probable than in any other plastic operation. For his sutures he uses the finest possible silver wire; it is drawn to order.

As regards the result of the operation on various symptoms that were supposed to arise from the presence of the injury, he has experienced the greatest success and greatest disappointments. In some, local treatment would have answered every purpose. The most expensive present he ever received from a patient was from one on whom he had performed this operation, and relieved by it a morbid mental condition that had lasted for years, with great local stress and inability to walk any distance or to stoop over in packing a trunk.

Dr. A. H. Smith knows well the value of preliminary treatment, and employs it faithfully; but there is a limit to the endurance of a patient. She cannot be kept too long upon her back, and it sometimes becomes necessary to operate before all that is possible has been accomplished. In some cases there is an unavoidable tension, and in others a friable condition of the tissue, which is benefited by leaving the stitches in position. He allows the patient to attend to her domestic duties with the sutures *in situ*. In his experience there has been no relation between the number of children and the tendency to carcinomatous degeneration. Such growths have been in women who have had but one or two children only. Cancer of the mammary gland is most common in sterile women, or when children have been few. He has rarely seen cancer in its early stages in an enlarged cervix with ectropium, but, on the contrary, in unnaturally small cervixes.

Dr. Wharton Sinkler has three patients who have been operated upon for lacerated cervix, one of them by Dr. Goodell. All of them have since become pregnant.

Dr. Montgomery remarked that one-sixth of the cases he had operated upon (within four years) had since become pregnant. He thinks Dr. Smith's suggestion an over-true one. As the injury was the result of pregnancy, the risk must not be run again. In the Philadelphia Hospital he has found cancer of the uterus most common after numerous labors. The same rule has held good in mammary cancer. It has been most common after frequent nursing.

Uterine hyperplasia is reduced by operating on the torn cervix. He has operated with this result in view in cases of so-called subinvolution. Dr. — divides the cervix and removes a wedge-shaped piece, reuniting the wound, as a remedy for this condition.

Dr. H. Beates has performed twenty-three operations, and has had two pregnancies since. He has had under his care seven cases of uterine carcinoma, and in all of them cervical laceration co-existed. The number of children varied from one to several.

Dr. Baer, in closing the discussion, remarked that in answer to a letter of inquiry to the husband of a patient upon whom he had operated to restore the cervix, he received one in return in which the idea of another pregnancy was scouted with disdain.

EDITORIAL DEPARTMENT.

PERISCOPE.

Brandy Poisoning.

Dr. J. A. Owles says in the *Lancet*:

On Tuesday, May 16, I was summoned to see a gentleman in a "fit," and found him lying on the floor of his bed-room in a deep sleep, with evidence of having recently vomited, and with a slight bruise on the right temple and another on the right thumb, which confirmed the supposition of a fall. His breathing was labored, but not exactly stertorous: his heart's action was very weak, and his pulse variable; the pupils were unequal, the left being a good deal contracted. It was difficult to rouse him, and impossible to get any information from him. A lady and gentleman (relatives) and the proprietor of the house in which he was lodging were present, but could throw little light on the history of the case. They said that he had come to Bournemouth for change after a very severe attack of inflammation of the right lung, that he was a little over thirty years of age, that he had been walking about "too much," and that he had been complaining of neuralgia. A friend had given him, a few hours previously, a glass of port wine, and he had also taken a "little" brandy. He had been sleeping a good deal upon the bed during the morning, but was not heard to fall, and no one knew what had happened until he was found upon the floor. Three bottles were upon the mantelpiece: one containing a tonic mixture with steel in it; a second, some creosote for local application; and a third was an ordinary brandy bottle half full. There was no reason to suspect poisoning, either wilful or accidental. The only odor perceptible in the breath was that of brandy, and it seemed unlikely that this was the cause of his illness, as he was an habitual abstainer from alcoholic drinks. We undressed him and used mild measures to keep him from sleep until we could ascertain more accurately his condition.

As soon as his clothes were removed, Mr. T. B. Scott, surgeon, of this town, who had also been sent for, entered the room. We then gave a little ammonia with belladonna, and some coffee, and put mustard to the legs and strong smelling-salts to the nostrils. The vomit, which had previously been scanty and somewhat like froth and treacle, was now much increased; inequality of the pupils was more marked, and the difficulty of keeping him awake was greater; but with the remedies named we aroused him sufficiently to get his own account of what had happened. He admitted, in reply to close questions, that he had taken during the day, in six to eight hours, about half a bottle of brandy for the neuralgia; and added that, though an abstainer, he always took it when suffering pain. It was evident, therefore, that this was the primary cause of his fit, and that the brain pressure resulted from it. Being convinced of this, we allowed him to sleep, watched by a nurse, and left him for two hours; at the expira-

tion of which I returned and found him somewhat better, though still drowsy.

May 17th: The patient had passed a fair night and felt much relieved, but there was still inequality of the pupils and partial loss of sight in the left eye. He also complained of a "creeping" sensation at the "top" of the head near the centre, and occasionally extending to the forehead and eyes. I gave some bromide of potassium and gentian, with a little aconite for the neuralgia, and a dose of calomel with rhubarb for the bowels.

18th: The pupils nearly equal, the sight of left eye normal, and the "creeping" sensation less. He then gradually improved, till one week after the "fit" he was well enough to return to London.

I have recorded the case for two reasons: First, because of the combination of symptoms of alcoholic poisoning and apoplexy obscuring diagnosis; secondly, because of the somewhat remarkable effect of half a bottle of brandy upon an habitual abstainer.

Cerebral Dyspepsia.

Dr. John S. Main, in the *Brit. Med. Jour.*, strongly insists on the purely cerebral origin of many forms of dyspepsia, where the patient is neither overindulgent, nor intemperate, nor addicted to hurrying over meals, nor accustomed to eat coarse or unwholesome food. The cerebral form of dyspepsia is well seen, in many cases, where a healthy man, with a good appetite, suddenly receives bad news when sitting down to a meal. "But, perhaps, of all conditions acting on the brain in this manner, and through the brain on the stomach, no one is more injurious, or more jarring to the cerebral elements, than uncertainty, and the worry caused by the same, more particularly in preternaturally irritable subjects. In fact, it is in connection with this same worry that the form of dyspepsia I have at present under consideration most frequently occurs. The mind, in such cases, preys upon itself; the cerebral elements seem to get jarred and out of gear; and with this condition the stomach sympathizes. But in addition to worry, the habitual practice of calling into action the "reserve fund" of the cerebrum, as already mentioned, will bring about the same consequences—namely, cerebral fatigue and exhaustion, indicated chiefly by preternatural irritability; this condition, sooner or later, telling upon the digestive organs. Having said this, it is almost unnecessary to add, that such cases are most commonly met with amongst those who are engaged in the hottest part of the 'battle of life,' or 'struggle for existence;' and, again, amongst these, chiefly those whose business or profession leads to much anxiety, uncertainty, or overstretching of the mental powers. In over-aspiring, over-ambitious natures, 'hope deferred' may bring about the same results; as, according to the biblical expression, 'it maketh the heart sick.' My attention was drawn to several cases of dyspepsia

connected with one or other of these conditions, some time ago; and what made me more strong in my view of these cases being cerebral, and not stomacic at all in their origin, was their obstinacy under all forms of natural treatment. Latterly, I have found that the only treatment capable of doing these cases any permanent good, is a change, in the wide sense of the term—a relaxation from business or study; and as regards medicines, not such as are meant to act on the stomach directly, but those meant to act on the cerebrum. Amongst these, I have found the most useful to be the bromide of ammonium or bromide of potassium—preferably the former—given in a sufficient dose at bedtime to secure a good night's sleep, this being often very indifferent, and so tending to complicate the case; and, combined with this, to be taken three or four times during the day, such medicines as are known to have a building-up effect on the nervous system—amongst these, the most useful being phosphorus, or the hypophosphites, and cod-liver oil. Arsenic and quinine are often also useful, and a generous diet is always indicated. Unless the stomach has passed into a state of disease (which it may do, if overtasked when in this weakened state), any of these medicines are generally well borne. It will be well to bear in mind, however, that if the mucous membrane of the stomach be in a state of irritation, quinine, arsenic, phosphorus, the hypophosphites, and sometimes even cod-liver oil, are generally inadmissible."

The Agency of Micro-Organisms in Decay of Human Teeth.

The *Dental Cosmos* for January, 1883, publishes a paper on this subject, read by W. D. Miller, of Berlin, before the American Dental Society, of Europe, at Ostend, from which we note the following conclusions:

1. The first stage of caries of the teeth, *i. e.*, the extraction of the lime-salts, is for the most part caused by those acids which are generated in the mouth by fermentation.

2. Decalcification of the enamel signifies total destruction of that tissue; of the dentine there remains after decalcification a tough, spongy mass, which becomes subject to the invasion of enormous numbers of fungi (leptothrix-threads, bacilli, micrococci, etc.).

3. The leptothrix-threads are found, with rare exceptions, only upon the surface, or in the superficial layers of the softened dentine, and appear to take but a small part in the invasion. The bacilli, on the other hand, penetrate far into the dentine, even into the finest branches of the canaliculi. Micrococci penetrate furthest.

4. In the separate tubules is frequently to be seen a gradual change from leptothrix-threads to long bacilli, from long to short bacilli, and from the latter to micrococci.

5. The fungi produce anatomical and pathological changes in the deeper layers, stop up the canaliculi, and necessarily lead sooner or later to the death of the dentinal fibrils. The outer layers of dentine, thereby deprived of nourishment, die and fall a prey to putrefactive agents.

6. The invasion of the fungi is always preceded by the extraction of the lime-salts.

7. The fungi have not the power either to

penetrate or to decalcify sound dentine, so that the infection of a perfectly sound tooth by a carious one seems to be excluded.

8. We may accordingly look upon caries of the teeth as consisting of three stages: (1) decalcification; (2) infection and devitalization of the decalcified dentine; (3) putrefaction of the devitalized dentine; though it would not be easy to say just where the one stage ceases and the other begins.

9. I have in a number of cases been able to establish the participation of the fungus *saccharomyces mycoderma* (?) in the carious process.

I do not, however, wish to be understood as saying that acids, or pathogenic bacteria, or putrefactive bacteria, or all together, are the sole and only cause of decay of the human teeth. What I am prepared to say is this, that in my opinion there is not a single case of caries in which micro-organisms do not play some part, and that in the most cases they play a very important part.

Dialyzed Iron.

The *Chemist and Druggist* says that Dr. Prosser James has lately said, in a summary of the position which dialyzed iron is entitled to hold in medicine, that the persalts of iron are frequently employed solely on account of their astringency, while the protosalts are occasionally considered as being destitute of this quality. The freshly-prepared carbonate is an excellent mild chalybeate, but difficult to keep in an unaltered state, so that preference is given to reduced iron. The scale preparations of iron are held in repute, both from the extreme facility of their use, and their agreeable taste. When these three forms of iron are inadmissible, dialyzed iron may be resorted to with admirable effect. It is a milder chalybeate than the three preceding, and does not produce the slightest irritation.

A recent analysis by Professor Tichborne of Wyeth's preparation agrees almost exactly with Graham's statement, that dialyzed iron contains 98.5 parts of the oxide and 1.5 parts of hydrochloric acid. The liquid thus obtained differs altogether from an ordinary solution of salts of iron, by its not giving rise to the blood-red color on the addition of alkaline sulphocyanide, nor to the blue precipitate with ferrocyanide of potassium. It does not become cloudy on boiling, nor when agitated with two parts of ether and one part of alcohol is the ether layer colored yellow. It is so sensitive that ordinary spring water will cause a precipitate, yet no precipitate is produced by nitric, acetic, or muriatic acid. Graham's solution gelatinized in about twenty days, and he regarded it as a solution of colloid ferric hydrate, which, he considered, existed in both a soluble and insoluble form. It is, however, never free from chlorine. Theoretically, therefore, the liquid is a solution of a basic oxychloride, but it can never be imitated by dissolving saturated solutions of the hydrate. All these artificially-made liquors are astringent, with ferruginous taste and acid reaction.

Respecting the therapeutic value of dialyzed iron, of which there has lately been some inclination to doubt, Dr. James says there is no question. By the method now followed of counting blood-corpuscles, it is found that the taking of dialyzed

iron both increases their number and improves their condition. Dr. James gives, as an average dose, twenty to fifty drops, daily, in three doses. Dr. Weir-Mitchell, of Philadelphia, gives as much as a drachm at a time.

Specimens have appeared in the market which are not only innocent of any acquaintance with a dialyzing membrane, but seem little else than diluted solution of perchloride of iron.

Naked Eye Anatomy of the Female Genital Organs.

Before a recent meeting of the Edinburgh Obstetrical Society (*Edinburgh Med. Jour.*) Dr. Hart said:

The point I wish to clear up is easily understood. In the anatomical descriptions of the external genitals, the fourchette and labia minora are stated to be mucous membrane. Anatomists have described them thus, in error, owing to the fact that the external genitals in the cadaver soon get altered, and have a misleading appearance to the naked eye. In the living female, however, it can be readily seen that the fourchette is skin, and that the labia minora are also skin. If I am asked on what I base this statement, I reply that to the naked eye these structures have the appearance of skin; and, further, that the line of separation between skin and mucous membrane can be clearly seen not to include them. Hilton has already noted that at the anal aperture the line of separation between skin and mucous membrane is perfectly distinct, and he terms it the white line. This line is of great importance in determining the fact as to whether piles are external or internal. If the external genitals be looked at carefully, we can trace the line of demarcation between skin and mucous membrane as running along the base of the inner aspect of each labium minus, and passing into the fossa navicularis, separating its skin boundary, the fourchette, from the mucous membrane over the hymen. While Garriguez has drawn attention to the error in the statement that the fourchette is mucous membrane, no one, so far as I am aware, has pointed out the true structure of the labia minora. Turner, however, has described them as muco-cutaneous. The exact relation of the external genitals to one another is of interest. The labia majora have their under surfaces in contact, whatever posture a woman may assume. The labia minora are also in contact, and the fossa navicularis is artificially made when the fourchette is hooked down. This exact apposition of the external genitals has, of course, a protecting influence on the sensitive organs.

The President thanked Dr. Hart for drawing the attention of the Fellows to this point in anatomy. Though it might seem of small moment, it might be of pathological importance in explaining warts and other growths on the nymphæ. Since Dr. Hart had directed his attention to this point, he had examined several cases, and could confirm Dr. Hart's observation.

Pessaries in Minor Displacements.

In the course of a lecture on this subject—*Medical Times and Gazette*, December 30, 1882—Dr. J. Matthews Duncan says that intra-uterine or stem pessaries are the only instruments you

can rely on for straightening the uterus, or keeping a flexion undone. They do this as a male bougie straightens the urethra. The patient's mind must be guided, and you must take care not to let any harm come through your treatment. You may replace a descended or retroflexed or retroverted uterus, and keep it replaced by a pessary, and you may so relieve or remove pains. You cannot cure a displacement, though sometimes you can substitute one displacement for another; that is, for example, change a retroversion into an anteversion. No doubt a displacement may sometimes be, in a sense, cured—as when an adhesive perimetritis ends in tying a uterus up to the higher part of the sacrum. One of the best examples of relief by a pessary is observed in the anteversion (by probe) of an engorged, retroverted and descended uterus.

Here a well-fitted Hodge is comforting and curative, maintaining the anteversion, elevating the uterus, or preventing descent on walking or standing, and preventing relapse into retroversion or retroflexion by keeping the posterior laquear of the vagina pressed against the sacrum.

Another notable example of relief is seen in descent with tendency to cystocele, when the irritation of the cystocele pushing at the orifice of the vagina is most annoying. In such, a suitably sized Hodge, or India-rubber ring, often, by its anterior limb, just catches the cystocele and obviates the tendency to protrusion through the os vaginæ. For each case your pessary must be specially adapted—a boat-shaped or a double-curved—and it must fit the patient in size and contour. Nothing can instruct you in this but bedside experience. A pessary, if it is to be useful, will give relief at once, and will need very little attention from you. If you are frequently fitting and re-adapting, you are almost surely doing more harm than good. A well-fitted pessary may be worn for months without being attended to. You must take care that the pessary does not cause ulceration and cut the vagina, and you must have a new one placed when the former one gets decayed. You will find it hard to get any good from a pessary unless you have a fair amount of perineum to support it. A pessary will be inefficient if the vagina is not long enough and capacious enough to allow of its action without strong pressure on the vaginal wall.

A Foreign Body in the Ear Nearly Twenty Years.

In the *British Medical Journal*, February 3, 1883, Dr. Lucius Holland describes the following case:

"A woman aged 27 came to the dispensary complaining of frequent headache and giddiness. According to my custom in these cases, the ears were examined, and a black mass of cerumen being visible in the right ear, she was referred to my clinic for diseases of that organ. Some difficulty being experienced in clearing the canal, a probe was employed, which at once came into contact with a hard body; and its impaction required the further use of forceps for removal. This body, upon examination, was found to be metallic, in the shape of a grape-stone, with very sharp apex, and weighed twelve grains. It was kindly tested for me by Mr. Leopold Dean, analytical chemist at Sir William Armstrong & Co.'s, and proved to be

a globule of iron. The patient had lived in the neighborhood of ironworks from the age of three until ten years, and as a child played and rolled in the sand. During the latter part of this time she suffered from pain in the right ear, for which the workmen puffed in tobacco smoke. At the age of ten years she was removed from the locality, and since then has resided in such places where no opportunity was afforded for the introduction of such a body, besides having no recollection of anything of the kind happening during the seventeen years. The globule of iron will, therefore, have been in the ear nearly twenty years. It was imbedded in dense cerumen, occupying the deep part of the canal, the circumference of which I observed to be irritated; the membrana tympani was somewhat depressed and thickened, with alteration of the 'cone of light.' Hearing has not diminished, and since the removal of the foreign body the giddiness and headache have ceased. After the age of ten years, the earache subsided as the calibre of the canal increased. This case may be regarded as a most remarkable instance of a dangerous foreign body remaining for years in the ear without serious and alarming consequences."

Nocturnal Enuresis Treated by Voltaic Alternatives.

Dr. Julius Althaus describes the following case in the *British Med. Jour.*, January 20, 1883:

In June, 1882, I was consulted in the case of a boy, aged 15, who had suffered from incontinence of urine during sleep, ever since he was nine years of age. He had been treated with belladonna and other medicines without relief; and as he was about to enter a public school, where a continuance of this trouble might have been particularly annoying, the parents were very anxious that something more should be done. The boy's general health was good, but he was considered a nervous child, and highly sensitive. There were no ascarides, but he had a very long prepuce, which could only with difficulty be retracted. There was, however, no suspicion of masturbation. Treatment by electricity having been recommended, I applied the middle-sized circular cathode over the region of the bladder, and the large oblong anode (five inches by two) to the lumbar portion of the spine—the current-strength, 2.50 milli-amperes, for five minutes at a time. As after a few such applications no material benefit appeared to have been gained, I then added fifty voltaic alternatives produced in the metallic circuit. The night after this was free from the usual annoyance, and the boy has made an apparently uninterrupted recovery.

Pepsina Porci—How to Get It.

The *Druggists' Circular*, January, 1883, says: For those who wish to be at the trouble of preparing their own pepsine, we can recommend the following simple process, first published by Dr. Lionel S. Beale, F. R. S., in the *Archives of Medicine*, Vol I.:

"Procure some fresh hogs' stomachs, slit them and remove the contents; then dissect the mucous membrane from the muscular coat, so that it can be laid smoothly on an even board. Wash it carefully with water, then squeeze the pepsine

from the mouths of the glands by firmly scraping the surface with a paper-knife. Spread the mucus thus obtained in a very thin layer on plates of glass, and dry quickly before the fire at a temperature of about 100° F., a current of air being allowed to play freely over it. In twenty minutes or half an hour it is perfectly dry, and can be scraped off and powdered in a mortar.

"The quality of the pepsine is estimated by the quantity of albumen that it is able to dissolve in a given time, when mixed with dilute hydrochloric acid."

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—*Lippincott's Magazine* for February is full of the usual interesting matter. Few of our monthlies surpass it in excellence of choice in contributions, and its illustrations are all of a high order of merit.

BOOK NOTICES.

The Systematic Treatment of Nerve Prostration and Hysteria. By W. S. Playfair, M. D., etc., Philadelphia. H. C. Lea's Son & Co., 1883. Svo., pp. 111.

The treatment of nerve prostration by electricity, massage and isolation, systematically combined, was first fully set forth by Dr. S. Weir Mitchell. In the volume before us Prof. Playfair gives a number of cases, details of treatment, and minute directions for carrying out the plan. It will be found a useful little manual by all who have this class of cases under their care.

Experimental Pharmacology: a Hand-book of methods for studying the physiological actions of drugs. By L. Hermann. Translated with notes and additions by Robert Meade Smith, M. D., Philadelphia. H. C. Lea's Son & Co. Svo. pp. 201.

How much or how little benefit therapeutics derives from the study of the physiological action of drugs is still a much-debated question. But to those who have faith in that method of investigation, this handy volume will be found a very complete and satisfactory guide. It is divided into two parts, the one a study of the action of a poison on isolated organs; the other an investigation of the general action of poisons. The directions are clear and brief, and the scheme for correct observation is very lucidly defined. Much of the merit of the book is due to the translator, who has added copiously to the rather barren text of the original.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

THE MISSING LINK.

An enterprising London showman has on exhibition a human being whom he glowingly advertises as "Krao, the so-called missing link."

This child is creating a great stir in unprofessional circles, and a large number of medical men were invited to a private view. Except her extreme hairiness, she exhibits no signs of physical degradation below the type of her race, and the *Medical Press and Circular* very sensibly points out that she is simply an exceedingly hairy Siamese child.

Several years ago, photographs of the hairy family of Siam were exhibited in England, and it is well known that the king of Siam bribed a man to marry the first hairy woman in the family, who transmitted the characteristic hairiness to her offspring of both sexes. Attention is called to the fact that Darwin again and again expressed his belief that the progenitors of mankind became divested of hair at an extremely remote period, before the several races diverged from a common stock, and before that common stock became erect. The discovery of a hairy race living in a tropical climate at the present day would therefore be almost more opposed to his theory than in favor of it.

The truth is that a copious growth of body hair is characteristic of the higher rather than of the lower races of mankind, and is a distinctive mark of the Semitic and Indo-European families; whereas, amongst the Northern Asiatic Mongols, Hottentots, and Bushmen, there is a scanty or scarcely perceptible crop of hair on the trunk and limbs. It used to be believed that extreme body hairiness was, at least in one instance, a national or tribal trait, and that the Ainos, the inhabitants of Jeyo, Saghalien, and the Kuriles, exceeded all nations in the world in this respect, possessing an almost animal-like covering of fur on the upper part of the body. But recent observers have greatly modified this exaggeration, and shown that, as regards hairiness, the Ainos could not even be compared with European sailors. No doubt one of the most permanent physical charac-

teristics of man is his covering of hair; and variations in its color, length, and distribution, as well as in the form of the hairs, as seen on horizontal section, afford valuable assistance in classifying and determining the affinities of the races of mankind; but instances of extreme hairiness like that seen in Krao must be put in a category by themselves. There are instances of a sport or variation arising we do not very well know how, and capable of transmission to offspring, and are indeed analagous to those cases of alteration of the cutis, or ichthyosis, which have been noticed from time to time in groups in the same family, as, for instance, in Edward Lambert and his sons—the celebrated porcupine family—who were publicly exhibited in England, France, and Germany, in the middle of the last century, and who were doubtless provocative of much learned and ingenious speculation in their day and generation. To quote or adduce such cases, however, in proof of man's descent from the apes, is either reckless audacity or profound ignorance. As well might we adduce cases in which children are born *minus* two fingers in evidence of his descent from the three-toed sloth, or cases in which there is a growth of a horny excrescence on the scalp as indicative of his close alliance to the unicorn.

So while this girl may put money in the show-man's pocket, her presence will not do much towards enlightening the followers of Darwin.

THE NOTIFICATION OF INFECTIOUS DISEASES.

It is always gratifying to have the results of experience prove the wisdom of certain acts. So then is it pleasing to the sanitarian, when he can adduce undeniable facts to prove the wisdom of his efforts to stay the ravages of contagious diseases, and to protect his fellowmen from their malign influences.

It has been recently stated by the Chairman of the Public Health Committee of Edinburgh that the experiment of the notification of infectious diseases has been carried on in Edinburgh since 1879 with great success, and his last report to the Town Council showed that during the year 1882

no fewer than 7,063 intimations had been sent in to the authorities by the medical practitioners of the city, and that not the slightest objection had been raised to the system of notification by any of the numerous medical men, or by the rate-payers. Personally, this gentleman testifies to the great assistance the arrangement has afforded the Health Committee and their officials in preventing the spread of infectious diseases; on a former occasion he alluded to outbreaks of small-pox, which the early information, thus obtained, enabled them to stamp out; and last year he had to record that several outbreaks of typhus, which formerly was the great scourge of Edinburgh, were promptly dealt with and localized, so that both mortality and expense were saved to the citizens. The death-rate of Edinburgh for 1882 was 18.54 per 1,000, and zymotic diseases contributed 9.90 per cent. of the mortality as compared with 13.20 per cent. for 1881.

The proposal to make this notification compulsory has many violent opponents in various portions of Great Britain, even to-day; but after careful reading of the literature of the subject, we are forced to the conclusion that all this opposition rests on the selfish ground that medical men are fearful of losing their patients, if they give notoriety to the existence of a disease that calls for removal and isolation.

That such a motive is unworthy the votaries of our dignified calling, needs no proving. The point we desire to make is, that *compulsory* notification of infectious diseases is a void that needs filling in the sanitary legislation of our own country. "Pro bono publico" must be our motto; individual desires must be subordinated to general good; for to secure complete *isolation* we must have *compulsory* notification.

DEVELOPMENT OF THRUSH IN TYPHOID FEVER.

During the recent epidemic of typhoid fever at Paris, M. Damaschino and M. Duguet reported a number of cases of thrush developed in the course of the disease. In M. Duguet's service, which contained at one period eighty typhoid fever

patients, more than half were affected with aphthæ, which first appeared on the pharynx and soon became so confluent as to form extended white patches, very much resembling the membranous patches seen in diphtheria.

In most cases, however, a number of separate distinct aphthæ were found about the patches. Such cases were also observed by M. Duguet among his private patients, generally in cases of gravity. In all cases there was considerable dysphagia, the patients were unable to swallow, and in some cases vomited all that was taken on the stomach, to such a degree that it was feared they would perish from inanition.

There was no difficulty experienced in removing the exudation, exposing the excoriated mucous membrane; frequently in 24 hours, through repeated swabbing with mel boracis and a concentrated solution of bicarbonate of soda, the patches entirely disappeared. But the aphthæ showed a remarkable tendency to reappear on the surfaces originally affected, and it was necessary to devote a considerable time each day to the care of these patients. In two very grave cases of the adynamic type, the greatest difficulty was experienced in nourishing the patients; they presented constantly recurring patches, which did not disappear at the period of convalescence.

They suffered considerably on any attempt at swallowing, and vomited every kind of liquid, bouillon, milk, wine and water, etc., and this to such a degree that they became exceedingly pale and feeble; in fact, there was every prospect of a fatal issue, without any of the ordinary complications of the period of convalescence.

M. Duguet was convinced that these dangerous symptoms were due to the extension of the aphthæ to the œsophagus and stomach, and administered from three to four grains of bicarbonate of soda daily in milk or water, continuing at the same time the frequent swabbing of the throat with alkaline lotions. A favorable change was obtained in a very few days, there was less dysphagia, and bland liquids were taken without inducing vomiting; in less than eight days, soups and eggs could be given, and after fifteen days

they were able to be about and take food the same as the other convalescents. Such was the treatment M. Duguet found most applicable in severe cases of this complication.

THE RISKS OF MEDICAL PRACTICE.

We have had occasion to refer in the past to the serious risks that physicians run, in the general practice of medicine, of being injured socially and professionally through the unfounded charges of bad, designing, or hysterical women. Two recent cases cause us to again utter a word of warning.

In England, a young girl came to a physician, complaining of morning sickness, headache, and total suppression of menses for five months. Suspecting pregnancy, he refused to give any emmenagogue medicine, as he was asked to do. An examination was made, with the girl's full consent, and the physician's suspicions were confirmed. The patient left, and the next thing the doctor heard was a summons for assault. Fortunately, he was able to produce the evidence of three visitors and three servants, who were all within ear-shot at the time, yet heard no outcry. The charge was at once dismissed. The other case occurred in Canada. A physician who had attended a woman for miscarriage, subsequently visited her (three weeks later) for some uterine trouble. Requesting her little boy (ten years old) to leave the room, he suggested a vaginal examination, which was made. He was subsequently charged with assault, which charge was afterwards modified so that it seemed that the woman yielded to his persuasion. The husband wrote to the doctor, offering to compromise for \$200. The doctor refused, and determined to stand trial. The little boy was coached to testify that, going into the back room, he saw, through an open door, the doctor leaning over his mother, and heard her say, "What will my husband say?" In rebuttal, it was proved that this door had not been open for months, and that both man and wife were disreputable and unworthy of belief. The doctor was triumphantly acquitted.

Happily, such cases are rare in our country,

but they are liable to happen at any time, to any physician; and, even though acquittal results, yet such a charge leaves behind it a cloud well calculated to prove a loadstone on the reputation and prosperity of the physician.

To avoid the possibility of such a calamity, it should be made an absolute rule, admitting of no exceptions, that examinations of women should never be made save in the presence of reputable witnesses; and further, the leaders of the profession in a district should unite to prosecute, to the fullest extent of the law, any one who prefers such serious charges when they have been proven to be false and groundless.

We congratulate the Canadian doctor on his manliness in fighting this charge.

NOTES AND COMMENTS.

Whooping Cough Remedies.

M. Pierre Vigier, in a French journal, gives a few prescriptions. First, he recommends Drosera to be given in the form of alcoholate for a child one to two years of age, twenty drops three or four times a day in a little sweetened water; for older children, from one to four teaspoonfuls in the course of the day. The favorite remedy of Dr. Delpech is one frequently employed in this country, namely, thirty grains of powdered cochineal and twenty grains of subcarbonate of potash in half a pint of water, flavored and sweetened. M. Vigier gives as a modification of this formula a recipe for a preparation which will keep, as follows:

Powdered cochineal,	15 grammes,
Subcarbonate of potash,	12 “
Boiling water,	600 “
Sugar,	900 “

Infuse the substances for half an hour, add the sugar, dissolve with a gentle heat, and strain. Children of one or two years may take two to three teaspoonfuls per day; older children, from three to six teaspoonfuls; and adults, two table-spoonfuls per day.

Dr. Beauchene prescribes the following powder:

Calcined magnesia,	8 grammes,
Sugar,	2 “
Extract belladonna,	20 centigrammes,
Kermes,	10 “
Orris,	60 “

Mix the extract and the sugar, add the kermes

and the orris, then the magnesia, and triturate to homogeneity. Divide into fifty powders. Children of one year may take three per day between meals; children from two to three years of age, five; and older persons, eight.

Sponge-Grafting.

Dr. P. W. Perkins Case contributes an article on this subject to the *Brit. Med. Jour.*, January 13, 1883. He uses the finest Turkey sponge, free from grit, etc., which he slices as thin as possible, and soaks in acid nitro-hydrochloric oil for two or three weeks, till all the calcareous and silicious matters are dissolved, when, after repeated washings with water, it has soft, velvety feel; this, neutralized by washing with liquor ammonia and steeping in carbolic acid solution (1 to 20) for twenty-four hours, is ready for use. A healthy granulating surface is required for it, preferably that of a burn, if there had been loss of subcutaneous tissue. First, he gently scratches the granulations till they bleed slightly, then places pieces of this sectioned sponge about the size of a shilling on the bleeding granulations, and they soak up blood, which, coagulating in the meshes of the sponge, forms thereby a temporary adhesion. The superficial wound-surface, if less than two inches square, is entirely covered with sponge; if more than about two inches square, about half, irregularly, with pieces of that size, and dressed after the Listerian method with oiled silk, six or eight piles of sanitas gauze, gutta percha tissue, and bandage. Sanitas lotion is generally used afterwards at the dressing, it being not so irritating as carbolic acid. The dressings are usually taken down the second day, and the grafts are then found firmly adherent by the coagulum, and comfortable; afterwards dressed every second day; but great discharge requires daily dressing. The sponge seems to become completely organized.

Lesions of the Isle of Reil.

The left third frontal convolution and the Isle of Reil are known to be the cortical centre for articulated speech: the memory of words, of spoken language. But that a part at least of the isle had also something to do with motion has long ago been taught; but cases with such lesions were rare, and experiments do not give always the same result, as it is almost impossible to injure alone that part of the brain. Pathological cases presenting such isolated lesions are therefore always interesting, and Drs. Raymond and Brodeur merit the thanks of the profession for reporting three cases of this character (*Revue de Méd.*, 1882, 7.)

They had thrice the opportunity to note in very aged individuals (twice hemorrhages, once softening), lesions which were strictly confined to the region of the *right* isle, and especially never spreading over the front wall. Clinically, the cases had the following aspect: hemiplegia attacking the contra-lateral extremities, leaving trunk and face unaffected; the arm was in every case attacked decidedly more than the leg; contractions and disturbances of sensation were not noticed. Skin—and sinew—reflexor as well as electric reactions were normal. Concerning secondary degeneration, nothing could be established on account of the early death of the persons, caused by other lesions.

The Mortality Referable to Alcohol.

A committee appointed by the Harveian Society of London to inquire into the mortality referable to alcohol have made their report, which is published in the *Brit. Med. Jour.*, January 20, 1883, and from which we take the following:

We find, therefore, upon the whole, reason to think that, in the metropolis, the mortality among any considerable group of intemperate persons will differ from that generally prevailing among adults in the following important particulars, *viz.*, a fourfold increase in the deaths from diseases of the liver and chylipoietic viscera; a twofold increase in the deaths from disease of the kidney; a decrease of half as much again in those from heart-disease; a marked increase in those from pneumonia and pleurisy; a considerable increase and an earlier occurrence of those from disease of the central nervous system; a marked decrease in those from bronchitis, asthuma, emphysema, and congestion of lungs; a decrease nearly as great in those from phthisis, and a later occurrence, or at least termination, of the disease; a very large decrease in those from old age, with an increase in those referred to atrophy, debility, etc., and the addition of a considerable group referred in general terms to alcoholism or chronic alcoholism, or resulting from accidents.

Convallaria Majalis.

To those who have been reading long accounts of this *new* addition to our therapeutic resources, the following from the *Med. Times and Gaz.*, January 13, 1883, will possess a peculiar interest:

"The '*Convallaria majalis*,' recently so strongly recommended by Russian physicians as a substitute for digitalis and otherwise, is, we may inform those of our readers whose botanical knowledge does not go beyond the plants of the Phar-

macopceia, the familiar 'lily of the valley.' In Ray's catalogue, '*Plantarum Angliæ*,' published in 1670, and dedicated to *clarissimo viro* D. Francisco Willughby, *armigero, amico et mecenati suo, plurimum honorando*, to whose labors he owed much of his materials, Mr. Ray gives the uses of the plant in medicine as follows: '*Usus præcipue in morbis capitis frigidis, ut apoplexiâ, paralysi, vertigine, epilepsiâ; hinc et in lipothymiâ. Insigne itidem errhinum exhibent pulverisati flores.*—*Schrod.*' As lipothymia is an old name for syncope, and is coupled with vertigo, a notion of its strengthening the heart's action seems to underlie the whole. Indeed, the apoplexy referred to may have been intended for cerebral anæmia."

Corrosive Sublimate.

The *Med. Press and Circular*, January 31, 1883, says that this powerful drug, whose virtues as an antiseptic were first made known to the world by R. Koch, is now rapidly coming into use. Tarnier employs it freely in his maternity hospital. Every attendant on entering the labor wards must wash the hands and arms in a solution of corrosive sublimate (1 in 1,000). The patient's genitals are bathed in a solution of the strength of 1 in 2,000; this is also the strength required for vaginal injections. He appears to be well pleased with the results.

Billroth has also been employing it as a surgical dressing in a case of suspected anthrax. A patient admitted into hospital had been in attendance on a sick ox, from the rectum of which he had removed masses of coagulated blood, passing the hand deeply into the cavity. Afterwards pustules made their appearance on the dorsum of the hand. It was this condition of the hand, with the attendant history, that led Billroth to a trial of corrosive sublimate, apparently of the strength of 1 in 5,000. No fever had set in after several days' employment of the antiseptic.

The Treatment of Delirium Tremens.

Death, no doubt, in delirium tremens arises from want of sleep, but the want of sleep arises from want of nourishment. So says Dr. F. P. Atkinson, in *The Practitioner*, January, 1883. He recommends half a tin of Brand's liquid essence of beef and half a pint of milk to be taken alternately every two hours, and all stimulants to be cut off: Twenty-five grains of chloral, with thirty minims of compound tincture of cardamom in an ounce of water, every four hours, after the beef tea, will be useful. By this treatment, the pa-

tient is generally free from delusions in thirty-six hours; but good strong liquid food should be taken less frequently for some days. When there have been from ten to twelve hours more or less continuous sleep, then it is advisable to give up the chloral, and give thirty minims of the compound tincture of gentian with five minims of the tincture of nux vomica three times a day for about three days. This restores the tone of the nervous system and stomach, and creates an appetite. A little tincture of euonymin may next be substituted for the nux vomica, and some Carlsbad salt may be given in the morning when required.

Therapeutic Items.

Dr. Hanawalt, of Galena, Kan., uses the Syrup of Yerba Santa to disguise the taste of quinine in solution, which he says is the best he has ever used.

Nitric Acid, as an application in chilblains, has been recommended. Equal parts of dilute *nitric acid* and *aqua menth. pip.*, are penciled on the toes, at first daily, then twice a day.

Dr. Spörer recommends that three to four lumps of hydrate chloral, 10.03=.006 grm. should be inserted into the hollow of a painful tooth, the chloral being allowed to dissolve. He has treated 38 cases successfully in this way, and has also obtained good results in several cases of hemi-crania resulting from carious teeth.

FINGER-NAIL POLISH.—Pure oxide of tin, tinted with carmine, and perfumed to suit. Apply by rubbing on the nail either with a finger or a nail-polisher covered with leather.

CLERGYMAN'S SORE THROAT.—Dr. Springstein recommends the following as a useful palliative, and in some cases, a cure for this troublesome disease: Tinct. opii., tinct. sanguinariae, aa fl. ʒ j.; balsam tolu, ʒ ij. M. Sig.—Twelve drops on a lump of sugar three or four times a day.

Fibrous Papilloma of the Bladder.

A young woman was troubled with passing dark-colored urine, while her general health remained good. She was treated for hematuria, with astringent injections for a year without any permanent benefit. Dr. Frederic Thorne, who reports the case in the *Lancet*, January 13, 1883, then forcibly dilated the urethra, and just within reach of his finger, felt a large soft mass, growing from a pedicle attached to the base of the bladder. Seizing it with forceps, he dragged it with a portion of the bladder through the urethra, and transfixing the pedicle with two sharp hooks, separated it with scissors. Some adjacent rough

patches were removed with the curette, the stump freely swabbed with tincture of iodine, and all bleeding having ceased, returned into the bladder, which was then injected with iced water, with about 10 per cent. tincture of iodine. A subsequent severe hemorrhage was controlled by gallic acid in forty-grain doses, twice repeated. Many clots were passed, and the woman made a complete recovery.

Recovery from Severe Rupture of Abdominal Walls.

Dr. P. J. Higgins, of Wilkesbarre, reports in the *Medical Record*, January 27, 1883, the case of a man who was thrown from a locomotive down an embankment. There were two extensive rents in the parietal layer of the peritoneum, while at least sixty square inches of the visceral layer were exposed to the atmosphere for over half an hour, and freely manipulated for over five minutes.

The abdominal walls were not cut, but torn clear through, as if burst, not from without, but from within. The patient was a vigorous, healthy, temperate man, which certainly contributed materially to his recovery; but the method of inserting the sutures was undoubtedly the main factor in the case.

These were inserted in such a manner, and drawn sufficiently tight, to produce a slight pouting of the lips of the wound, thus shutting off the silk from the cavity of the abdomen, which the exuded lymph, aided by the double pressure, soon sealed air-tight once more, thus preventing the entrance of pus, blood, or other irritating or foreign matters.

Bacteria and Puerperal Septicæmia.

Many investigators have been engaged in this field of pathology without having as yet given us any accurate data. The latest researches in this direction have been made by Dr. Ferdinand Karewski, of Berlin. He has found bacteria in the lochia of the healthy as well as of the sick, and the *Medical Times and Gazette*, January 20, 1883, notes his conclusions as follows:

He supposes that they are derived from the atmosphere; that they get into the vagina when this canal is opened up during parturition; and he points out that the conditions within the vagina as to warmth and moisture are highly favorable to the life, growth, and propagation of organic forms; and that under such circumstances they may, so to speak, cultivate themselves, and change under cultivation, till an exceedingly virulent bacterium is the result. If we admit that

such is the case, it explains why some lochia should be more dangerous than others, and why the later lochia should be more noxious than the earlier.

Erysipelas and Elephantiasis.

In the course of an address on "Diseases Allied to Erysipelas," Mr. Jonathan Hutchinson (*Medical Times and Gazette*), January 6, 1883, makes the assertion that we shall make a definite simplification in our nosology when we class elephantiasis as, in the main, a result of chronic and recurring erysipelas. All observers agree that elephantoid parts are prone to attacks of erysipelas; let us change the mode of expression and say, not that elephantiasis is liable to erysipelas, but that it is in a large degree the result of it. He has seen several cases in which some slight wound of the foot or leg, some sore on the genitals, around which inflammatory œdema has occurred, and from that œdema, the elephantoid process take its origin. He does not deny the influence of climate, race, and diathesis, as predisposing factors. He does not believe in the specificity of erysipelas, contending that it is simply an inflammation affecting the lymphatic spaces, but that it is capable of generating a virus that renders it contagious.

Papilloma of the Bladder.

The recurring expulsion of pure blood from the bladder, and its presence in smaller quantity in the urine at short intervals, pain radiating from the perineum to the penis and rectum, and inability to sweep the fundus and sides of the bladder with the beak of a Thompson's searcher, were the prominent points in a case reported by Dr. Joseph Ranschoff, of Cincinnati, in the *Medical News*, February 10, 1883. Cystotomy allowed the finger to come in contact with a fleshy mass (about the size of a peach) situated on the posterior wall of the bladder. It was not movable, and was firmly attached by a broad base. The écraseur was, therefore, useless. A Volkman's sharp spoon was used to scrape the mass, which came away in shreds and in larger masses. Not until a distinct excavation could be felt was the scraping desisted from. A slow-healing ulcer now took the place of the growth, and it was a year before the man fully recovered.

Post-Diphtheritic Atrophy.

In the ordinary form of post-diphtheritic paralysis there is not usually observed any atrophy. But Dr. Kahn records in the *Berlin Klin. Woch.* No. 1, the case of a boy aged fourteen, in whom

eight days after recovery from a mild attack of pharyngeal diphtheria, paralysis of the lower part of the œsophagus set in, which caused a return of the food ingested, which did not reach the stomach, as it was not of acid reaction. Then set in great atrophy, so that in June, 1882, the boy weighed only fifty pounds, notwithstanding good nourishment, which was introduced into the stomach by means of a tube, so long as the dysphagia lasted. The temperature was normal and excreta natural, so that it seemed as if only the process of assimilation was at fault. He finally improved in all respects, and in October weighed seventy-five pounds.

The Bacillus of Measles.

From the *British Medical Journal*, January 27, 1883, we learn that according to M. Le Bel, (Académie des Sciences), the bacillus is found in the urine in the early stages, and disappears with the fever; is a slightly curved, highly refractive rod, moving very slowly; it contains oval spores at one-third its length, in a bag of dead protoplasm, which gradually disappears, the spore showing then a zone of mucilage around it. Another occurrence of spores on the thirty-fifth day was observed in an adult. The bacillus also may be got from the skin at the later stages. M. Le Bel cultivated it, and injected it into a guinea-pig, which, on the tenth day, showed small bacilli in its urine, but did not seem incommoded. The urine in scarlatina and in diphtheria shows a microbacterium and a micrococcus, respectively both quite different from the "bacillus of measles."

A New Sign of Pregnancy.

Dr. Jorisen, of Liege, led to do so by the statement of Graves that the frequency of the circulation remains invariably the same in all positions when there is hypertrophy of the heart, has made observations with the object of ascertaining whether the hypertrophy which occurs during pregnancy would give the same result. As a result (*Brit. Med. Jour.*, January 28, 1883), he found that a woman who is pregnant has the same number of pulsations whether she be seated, lying down, or erect. But as an offset to this, Dr. H. D. Fry, of Washington, has made some observations on ten pregnant women, the results of which he reports in the *Medical Record*, January 6, 1883, as follows: "Taking the ten cases, we find that in five of them the pulse varied in the different positions from three to six beats, and in five cases from six to twenty." We await further developments.

A Treatment of Acne Rosacea.

M. Bouchut, in *le Paris Medical*, recommends the following preparation:

R. Aquæ Destill,	5 v.
Aq. Rosæ,	5 iij.
Spts. Camphoræ,	5 iiss.
Sulphur. Sublimat,	5 ss. to 5 j. M.

This is used as a lotion, and is applied to the affected parts at night with a soft sponge and allowed to dry. The next morning it is washed off with water as hot as can be borne, which has been previously boiled to rid it of all traces of chalky matters.

This treatment should be continued for some time, and when the pustules have disappeared, linear or punctated scarifications should be practiced, to divide the cutaneous vessels and induce complete cure of the redness and thickness of skin which remains.

Ligature of Common Carotid for Hemorrhage.

Mr. M. A. Messiter reports, in the *Lancet*, January 13, 1883, the case of a young man in whom, after catching cold, the left tonsil was found inflamed and enlarged. Subsequently, a swelling, like mumps, appeared externally. Three days later, without warning, profuse arterial hemorrhage occurred to the extent of three pints, when the swelling disappeared. After twenty-four hours, the swelling reappeared, and alarming hemorrhage occurred (even to the verge of syncope) with a like result. Considering that the proximity of so many large vessels would make it unsafe to select the external carotid, the common carotid was ligatured under antiseptic precautions, with a complete recovery.

Treatment of Typhoid Fever.

In an editorial on the recent epidemic of typhoid fever in Paris, the *Medical Record*, January 6, 1883, says that the conclusion to be drawn from the Paris epidemic, as regards the therapeutics of typhoid fever, is that the disease must be watched, not actively treated. We believe that the sooner this view is taken, and typhoid fever is looked upon as a disease like small-pox or scarlet fever, whose course the physician cannot greatly modify, but whose dangers we can, in part, avert, the better it will be for our science and our credit.

Pregnancy Complicated with Cancer of the Cervix.

Dr. Edis related to the Obstetrical Society of London (*Medical Times and Gazette*, January 6, 1883,) the case of a woman, six months pregnant, who, eleven months previously, had begun to suffer from pain, hemorrhage, and discharge.

There was epithelioma, involving the whole circumference of the cervix and the greater part of the posterior vaginal wall. Palliative treatment was adopted. When labor commenced, it was evident that delivery *per vias naturales* was impossible, so Cæsarian section was performed. The child was born in a state of suspended animation, but recovered: the mother also recovered, and when seen, eight months later, the disease had made but little progress.

Naphthalin as an Antiseptic.

From an article in the *Am. Jour. Med. Sci.*, we learn that naphthalin is available for all the purposes to which iodoform has been applied, and as yet no constitutional effects have been observed to follow its use locally. It is as powerful an antiseptic and "antibacteric" as iodoform, and has a less disagreeable [?] smell. Its application causes a slight transitory sensation of heat, but no pain. Anschütz states that very sensitive granulations sometimes bleed rather freely after it has been applied, owing to the sharp angles of the hard crystals. This can be obviated by using it in fine powder, though if there is much discharge it is then apt to form a crust on the surface of the granulations. When the crystalline form is used, the discharges escape freely.

Origin of White Corpuscles in Leukæmia.

Dr. G. Varios, a pupil of Robin, has instituted a series of observations to determine the origin of white blood corpuscles in leucocythæmia (*Journ. de l'Anat. et de la Physiol.* 1882, p. 266). He is of the opinion that the enlargement of spleen, liver, and lymphatic glands exerts no direct influence on the increase of the number of white corpuscles. In an enlarged liver of a case of leukæmia he found the capillaries dilated by white corpuscles, but no lymph-cells whatever in the interstices, and at the same time he did not notice any trace of biliary ducts in his slices. The latter fact is, as Dr. Friedländer remarks, a rather curious one, and would seem to throw some doubt on the reliability of Variot's observations.

Treatment of Prolapsus Recti by Langenbeck's Method.

The *Medical Record*, January 15, 1883, tells us that Turbin reports (*Mediz. Obozr.*, Feb., 1882), two cases of prolapsus recti cured by the subcutaneous injections of ergot (R Extracti secalis cornuti aquosi, ʒj.; glycerini, aquæ destill., āā ʒj. Solve. A syringeful.) In one of the cases the prolapsus was reduced by five injections,

in the other by nine. A swelling as large as a walnut formed after each injection, disappearing in one to two minutes under moderate massage by a finger. Pain, though invariably produced, was insignificant.

Local Medicines.

A retired surgeon is writing in the *Medical Press and Circular* some of his observations or fancies accumulated during his active practice. One of his notions is this: "That in particular districts of the country medicines seem to me to derive special efficiency when combined with certain agents. For example, in the cotton districts nitrate of potash seems singularly useful in combination with all sorts of other medicinal substances; in the iron districts, sulphuric acid seems to exercise a similar special influence; while in the coal countries nitric acid seems to be specially necessary." This subject is interesting, and worthy of further observation.

Abdominal Presentation.

Dr. Marchionneschi reports one case and refers to three others in the *London Medical Record*, Nov. 15, 1882. The dorsum was lying upwards, the abdomen underneath, masked by the agglomerated upper and lower extremities. He reached down a leg and found the umbilical cord so tightly twisted around it that it was difficult to pass a pair of scissors to divide the cord before bringing down another leg. The rest of the child followed easily and it was born alive, healthy, and well shaped. All progressed favorably.

Solution of Cayenne Pepper in Glycerine for Tinea Tonsurans.

In the *Mississippi Valley Medical Monthly*, Dr. G. W. Overall reports two cases of tinea tonsurans, where the head was almost bald, with a few dry, dead-looking hairs scattered over it; the dry scaly crusts extending all over the head. All the usual remedies were unavailingly tried. Finally the head was cleansed with a solution of sulphite of soda, and then on alternate days a saturated solution of cayenne pepper in glycerine was applied. This produced most satisfactory results.

Restoration of Frozen Persons.

The *Am. Med. Weekly*, January 6, 1883, says that some recent researches have very important bearing on the resuscitation of persons nearly moribund from freezing. Laptchinski (Knowledge) has made a series of very careful experiments upon dogs with the following results: "Of

twenty animals treated by the method of gradual resuscitation in a cold room, fourteen perished; of twenty placed at once in a warm apartment, eight died; while of twenty immediately put into a hot bath, all recovered."

Vesical Calculus with Hair-pin Nucleus.

Dr. W. R. Gillette presented to the New York Obstetrical Society (*New York Medical Journal*, January 27, 1883), a vesical calculus removed from a girl aged nineteen, whose symptoms were emaciation and incontinence of urine. The stone had a hair-pin for a nucleus. It was removed through the vesico-vaginal septum. The patient professed ignorance as to how the hair-pin had entered the bladder. He had a similar case some years ago.

Hæmatemesis in Chronic Splenic Tumor.

Dr. Wm. Osler calls attention in the *Canada Med. and Surg. Jour.*, to the fact that severe, even fatal hæmatemesis may occur at an early stage of the splenic trouble, even before the constitutional symptoms are marked. The importance of the fact is chiefly from the diagnostic standpoint, and in an attack of vomiting of blood, the attention should always be directed to the spleen as well as the liver, as a possible cause.

Treatment of Meniere's Disease.

Dr. Arthur Flint writes to the *British Medical Journal*, January 20, 1883, that he has had under his care for six months a case of this disease, which has improved greatly under the use of ammoniated citrate of iron, and the bromide and carbonate of ammonia. A liberal diet was enjoined, and severe brain work interdicted. When anæsthesia of the fauces and soft palate supervenes, the bromide is stopped for a short time.

CORRESPONDENCE.

Treatment of Rosacea by Leeching.

EDS. MED. AND SURG. REPORTER:—

Mrs. G. suffered with Rosacea for five years, and had undergone many forms of treatment with but little relief. Her case was a true type of the disease. About two years ago she consulted me for treatment. There existed no uterine trouble; and she said her health had always been good with the exception of the disease of the face. Her appetite was good, digestion fair, and bowels regular. I gave her occasional alterative doses of blue pill and calomel, and Fowler's solution with iodide of potassium internally, and used externally ointment of chrysophanic acid. In a month or two, the Rosacea began to disappear, and the

face became smooth; but the skin did not resume its natural appearance, but remained of a deep brownish color. She discontinued the medicine and considered herself cured, and remained much improved until a few months ago, when she again called my attention to her case. I found Rosacea had returned, with more boldness than it had shown two years before. The forehead and face presented a yellowish brown appearance. The nose, cheeks, and chin were studded with angry-looking pustules, from the bases of which radiated a deep erythematous hue. So reddened was the condition of the integuments of the cheeks, chin, tip and alæ of the nose, that I decided that neither medicine internally nor local applications could avail anything in removing the long-standing and extremely congested condition of the skin of the face. I advised the immediate application of a leech to each cheek, to the side of the nose, and to the chin; and directed that the bites of the leeches be allowed to bleed two or three hours. This was done, and I prescribed the following mixture and ointment:

R. Iodide of potash,	3jss.
Tinct. gentian comp.,	j.
Fowler's Solution,	ij.
Aqua. distil.,	vij.

Mix. Shake well and take a tablespoonful after each meal, and:

R. Chrysophanic acid,	grs. xx.
Vaseline,	3j.

Ft. ungt. Sig.—Apply to the pustules night and morning for a day or two, and then once a day. At the end of two weeks, the pustules disappeared, and the Rosacea was cured, leaving the complexion in a more natural condition than it had been for five years. I attributed the rapid disappearance of the Rosacea to the relief given to the extreme local congestion of the integument of the face, by the depletion produced by the application of the leeches. By this leeching, the injected and turgid state of the capillaries of the skin of the face was relieved, and a healthy circulation re-established in its stead. The leeching proved a vast improvement on the lancet-puncturing plan of relieving the congestion of the skin in Rosacea. J. B. JOHNSON, M. D.

Washington City, D. C.

A Diagnosis Wanted.

EDS. MED. AND SURG. REPORTER:—

On the evening of the 6th inst., I was called to see Miss P., aged 22 years. I found her suffering acute pain radiating from the upper cervical vertebra half way around the neck and down over the shoulders. The history of the case seemed to indicate a periodicity, disappearing towards morning, and recurring again towards four o'clock in the afternoon. My diagnosis was miasmatic neuralgia, and treatment, anti-periodic doses of quinine. On the evening of the third day after my first visit, her father came to my office and stated that she was much better, in fact without pain, and comfortable in every sense. On the following morning he again sent for me, and I found the following conditions present: circulation good, tongue heavily loaded and slightly dry on the tip, the pupils normal and responding

to light, a feeling of numbness on the right side, and partial paralysis as to motion, but normal as to sensation; the tongue was protruded in a direct line from the mouth, the mind perfectly clear, and no tenderness along the spine or pain in any region of the body; the respiration was somewhat hurried, but the lungs were clear throughout their whole extent. I had noticed a tendency to constipation, and received but a slight response from four c. c. pills administered the day before. There was a peculiar nervous excitation, for which I could discover no adequate cause. I prescribed:

R. Podophyll.,	gr. iij.
Capsicum,	gr. vj.

M. et Ft. Pil. No. vj. Sig.—One every 4 hours till bowels moved; and,

R. Potassii brom.,	3ij.
Ext. valerian,	ss.
Elix. simp.,	q.s. 3ij.

M. Sig.—Teaspoonful every two hours till nervousness subsided.

I called again in the afternoon and found patient just as in the morning, except the respiration, which was more hurried, and the tongue moist. Ordered a sinapism along the spine, and continued the above prescription. Inside of an hour I was called for again, and on reaching the house, in ten minutes after the messenger was sent, found that the patient had been dead for five minutes. She had died almost instantly, and without any apparent change in her condition. What was the trouble? Did death occur from pressure on the pneumogastric interfering with the heart and respiration? If so, why was not the interference with the circulation perceptible, as well as with motion on the right side? What caused disappearance of pain in neck while sensation remained intact till the moment of death? If occasioned by thrombus or embolism, why such marked periodicity with painless intervals? J. E. HOWE, M. D.

Greenfield, Iowa, February 13, 1883.

A Five-Franc Piece Swallowed and Vomited up After Lying in the Stomach Eighteen Days.

EDS. MED. AND SURG. REPORTER:—

Miss Ellen S., aged 17, single, came to me for treatment in September, 1874, when the following facts were elicited: During a scuffle with a friend over the possession of a five-franc piece, she placed it in her mouth for safe keeping, and inadvertently swallowed it. The coin lodged at the cardiac orifice of the stomach, giving her much pain, nausea and vomiting. The patient came to my office about three hours after the accident, and I saw at once that I could not extract the coin; I therefore took a probang and pushed it into the stomach, employing considerable force in the operation. Vomiting of blood, together with the contents of the stomach, at once followed, and continued at intervals for eighteen days, attended by emaciation and loss of strength and appetite.

Often during this time, whenever the coin changed its position, she would fall insensible, as though struck in the stomach by some instrument. The young lady frequently remarked that she "could nearly vomit up the money," and expressed the thought that it could be more easily done if the stomach were filled to repletion. She

accordingly filled her stomach to its fullest capacity with pancakes, and made ready to try the experiment. The first attempt was successful, the coin being ejected with such force as to knock out the two upper incisor teeth, and to loosen one bi-cuspid so much that it soon fell out. Large quantities of blood, mixed with the contents of the stomach, were thrown up, and the digestive power was greatly impaired. This condition of affairs lasted twelve months; and during the first three months it was with great difficulty that food of any kind could be retained in the stomach. Up to this time the action of the stomach showed ulceration, by the vomiting of blood and pus. These attacks of vomiting became less frequent and severe, and at the end of six months the patient seemed in a fair way to recover, and is now (1883) well.

NEWS AND MISCELLANY.

The Results of Improving the Milk.

The *Medical Record*, January 20, 1883, says that as a result of the improved quality of milk now brought to New York, the mortality among children under five years of age has decreased from 52 per 1,000 to 46 per 1,000.

The Massachusetts Medical Benevolent Society.

This Society held its twenty-fifth anniversary a short time ago, and celebrated it by a dinner. The event was a very enjoyable one. The object of the Society is to give financial aid to widows and orphans of medical men. The funds amount to \$20,000, and each beneficiary receives \$80 a year.

How to Officiate at a Funeral.

Through the efforts of the Commissioner of Health, Dr. Oscar C. De Wolf, a course of lectures is being given to those who officiate at funerals, in the Chicago Medical College. The course comprises lectures by Dr. Billings, Demonstrator of Anatomy, and a brief course in Chemistry by Prof. Hatfield. Instruction is also given in embalming. About thirty undertakers of the city are attending the lectures.

Professor Gross Will Not Retire.

In contradiction of the rumors that Professor Gross intends retiring from active practice, the veteran thus writes to the *Maryland Medical Journal*: "Will you kindly correct an error which crept into 'Our New York Letter,' issued in the last number of your valuable journal, and thus save me from becoming an idle and useless man during the remainder of my life? The writer of the letter is not responsible for the error, for he only repeats what the New York reporters said, without any authority, in their accounts of Dr. Sims' reception. I have not retired from practice, and have no such intention so long as I have eyes to see, hands to work, and a brain to guide my actions. I can not consent to lock up my ex-

perience, or to consign myself to ennui and obliviousness. I am determined to work to the end, whenever that may come.

"I am very truly your friend,

"S. D. Gross."

The "Hammond Prize" of the American Neurological Association.

A prize of five hundred dollars is to be awarded at the meeting in June, 1884, to the author of the best essay on the "*Functions of the Thalamus in Man*," under the following conditions:

1. The prize is open to competitors of all nationalities.

2. The essays are to be based upon original observations and experiments on man and the lower animals.

3. The competing essays must be written in the English, French, or German language; if in the last, the manuscript is to be in the Italian handwriting.

4. Essays are to be sent (postage prepaid) to the Secretary of the Prize Committee, Dr. E. C. Seguin, 41 West 20th Street, New York City, on or before February 1, 1884; each essay to be marked by a distinctive device or motto, and accompanied by a sealed envelope bearing the same device or motto, and containing the author's visiting card.

5. The successful essay will be the property of the Association, which will assume the care of its publication.

6. Any intimation tending to reveal the authorship of any of the essays submitted, whether directly or indirectly conveyed to the Committee or any member thereof, shall exclude the essay from competition.

7. The award of the prize will be announced by the Committee; and will be publicly declared by the President of the Association at the meeting in June, 1884.

8. The amount of the prize will be given to the successful competitor in gold coin of the United States, or, if he prefer it, in the shape of a gold medal bearing a suitable device and inscription.

Personals.

—Dr. Oliver Wendell Holmes, of Boston, is about to visit England.

—Dr. O. G. Cilley, of Boston, has been appointed Surgeon-General of Massachusetts.

—Dr. Samuel R. Rixey, a prominent physician of Culpepper Court House, Va., has been stricken with hemiplegia.

—Professor Huxley has been appointed the Rede Lecturer at the University of Cambridge for the ensuing year.

—Franz von Kobell, Professor of Mineralogy at the University of Munich, born on July 19, 1803, died on November 12th.

—Continental advices announce the death of the chemist Wöhler, to whom the world owes the discovery of aluminium. He was born at Eschersheim, near Frankfort-on-the Main, in 1809, and had for the past fifty years occupied a prominent position in the scientific world.

—Dr. W. G. Stedman, of Southington, Conn., was bitten recently in the hand by a pet squirrel; severe lymphangitis ensued, and it was feared he would lose his arm.

—The Sisters of Bon Secours, a Catholic order of unpaid nurses from Paris, have met with such success in Baltimore that they have sent home for assistance.

—Miss M. C. Thomas, daughter of Dr. James Carey Thomas, of Baltimore, has just been awarded the title "Doctor of Philosophy" by the University of Zurich, Switzerland.

—Dr. Bunsen, the German chemist, has been elected a Foreign Associate of the Paris Academy of Sciences. The dignity is one of the highest in the scientific world, and is limited to eight names. Dr. Bunsen succeeds the late Professor Wöhler, of Göttingen.

—The Duchess of Connaught has just recovered from typhoid fever, the malady which the Prince of Wales narrowly escaped, and of which the Prince Consort died. Now, Mr. Fawcett, the Postmaster-General of England, and his wife's cousin, are down with it.

—Chiari, the pathologist,* who has just been made professor at Prague, is a man thirty years old, who has already made over 8,000 post-mortem examinations. At a recent supper given in his honor, one of the speakers said he could not wish for greater happiness than that of being post-mortemed—if one may use the expression—by his friend Chiari.

Items.

—A whole family in New York were recently made very sick by eating smelts.

—The Electrical Society is the name of a new organization recently started in Chicago.

—The sum of \$1,029,953 has been appropriated for the public charities of New York City during 1883.

—Dr. Ogilvie Grant reports a case of rupture of the heart occurring during sleep. The organ was fatty.

—Dr. McCosh, of Princeton College, laments what he terms "the excessive indulgence in athletics."

—The buildings of the State Hospital for the injured of the anthracite coal region, at Ashland, are completed and ready for furnishing.

—Dr. W. H. Broadbent notes that a morbid condition which gives rise to convulsions, may in a less degree give rise to maniacal excitement.

—The past year brought death to the doors of no fewer than 22 eminent English medical men, and all were far advanced in age, the ages varying from 78 to 92.

—The Army Appropriation Bill as reported to the Senate abolishes the office of Assistant Surgeon-General, and appropriates \$15,000 for the purchase of books for the Army Medical Museum.

—Eighty thousand packages of tea were refused a landing in England, under the Adulteration act, during 1881 and 1882, and it is said much of it found its way into the United States.

—The late Professor Pond was once demolishing Darwin and his theories—a task which he frequently engaged in—when he triumphantly wound up with the question: "If we are monkeys, where are our tails?" The Professor, who had been speaking for two hours at a stretch before asking this poser, was startled to hear a tired auditor answer audibly: "We have sat on them so long that they are worn off."

QUERIES AND REPLIES.

MESSRS. EDS.—Are greatly improved instruments for operations or examination generally patented? If not, why not? Would it be unprofessional in a physician to patent an improvement? C. B. N.

Ans.—The Code of Ethics declares against patenting surgical instruments. In this we have believed it unwise, and at various times have assigned our reasons.

Dr. W. C., of Penna.—We are sufficiently well supplied with the back numbers you name. As a rule our reserve is sufficient; but of a few numbers we are short.

Official, Mich.—The Penn Medical College, of Philadelphia, has not been recognized by the regular profession in this city.

Cadmus, Ala.—The explanation of the cures of the "Mountain Evangelist," and all others like him, is either the effect of imagination (expectant attention), or the alleged cures are shams—"pious frauds."

C. H. F., Ala.—What is the relative value of beef essence as a nourishment in cases of great loss of vitality and consequent feeble digestion? Is it still regarded as one of the best agents for the relief of such cases, or does the profession generally share the opinion of Moleschott—that the nitrogenous constituents of the beef are, for the most part, coagulated, and thus rendered practically inutile by the process of boiling?

Ans.—Those physicians who do not use their own eyes, but see only through the fog of chemical and physiological theorizing, agree with Moleschott, and talk of beef essence as "merely a condiment." Those who are independent enough to look for themselves—still more those who have felt the effects of the substance in their own persons—know that the essence is a powerful and valuable nutriment.

H. E. Z., Lawrence Co., Pa.—Make an emulsion by using $\frac{3}{4}$ ij. each of sugar and gum arabic to each f. $\frac{3}{4}$ j. of a mixture of equal parts of turpentine and water, and flavor with oil of wintergreen grt.j. to the f. $\frac{3}{4}$ j. Graduate your dose that each may contain f. $\frac{3}{4}$ j. of the ol. terebinth. rect.

MARRIAGES.

CLEMENT—RICHARDSON.—At the home of the groom's father, in Levant, Me., December 24, by Rev. C. L. Banghart, Dr. W. B. Clement, of Biddeford, Me., and Miss Flora W. Richardson, of Oakland, Cal.

KYLE—GARDNER.—In New Bedford, Mass., by Rev. N. T. Whittaker, February 6, Flavel W. Kyle, M. D., of Boston, and Miss Mary L. Gardner, of New Bedford.

WAGNER—STEWART.—February 15, 1883, in St. Paul's church, Doylestown, Pa., by the Rev. V. Hummel Berg-haus, Dr. William H. Wagner, of York, Pa., and Miss Martha J. Stewart, of Doylestown.

DEATH.

BATES.—Dr. Joseph Nye Bates, a prominent physician of Worcester, Mass., died on the 22d, after a lingering illness, of heart disease. He was 72 years old.

LECTURE.

LARYNGEAL ACCIDENTS OF LOCOMOTOR ATAXY.

BY M. DREYFUS-BRISAC,

Physician to the Paris Hospitals.

GENTLEMEN: Hardly a week passes without some new memoir on the already complex semiology of locomotor ataxy, or as it is more generally termed, since the researches of Charcot, *tabes dorsalis*; but it is most frequently the varieties of the disease, formerly considered as abnormal, which are the object of special study.

As we have gradually come to be more expert in detecting the primary manifestations of the malady, first described by Duchenne, we find that the type traced by that eminent observer is more or less ideal, and rarely presents itself in actual practice. The anatomical lesions of *tabes* are evidently less localized than was formerly believed; its place is no longer among the forms of myelitis, but among the cerebro-spinal or bulbo-spinal affections.

Since the researches of Pierret have definitively introduced this doctrine, the diverse symptoms due to functional derangements or organic alterations of the cerebro-spinal sensory system can no longer be classed as abnormalities or complications, even if they appear at the debut, of the morbid processes.

During the past few years, the cerebral phenomena attending *tabes* have been the object of numerous works; the most recent are those of Joffroy and Hanot, Debove and Lecoq; if to these are joined the more recent researches on the ocu-

lar and auditory symptoms, it is evident that the description of *tabes*, affecting principally the bulb, is almost as far advanced as that of the disease following its usual evolution.

These cases are complex at a clinical point of view; for the different organs, under the dependence of the bulb, are simultaneously affected, and it is sometimes difficult to establish the origin and connection of the accidents observed. In this lecture we will consider only those cases where the larynx seems to be primarily or principally affected.

The principal observations and researches on the laryngeal manifestations of *tabes* have been made by French savants.

In 1868, M. Feréol, in a memoir read before the Société Médicale des Hopitaux, demonstrated the existence, during the course of locomotor ataxy, of laryngeal troubles, which Cruveilhier had merely mentioned.

Then, in 1874, in the thesis of M. Martin, a fact of the same order, communicated by Prof. Vulpian, is related. A number of observations followed, the most remarkable being that reported by M. Jean, as it was accompanied by a description of the post-mortem lesions, and led to the relation of two similar facts by M. Budin.

Towards the same period, M. Charcot, in his clinical teachings, definitively introduced these laryngeal attacks into the semiology of *tabes*, among the other visceral manifestations of ataxy, of which the type is furnished by the attacks of gastric pain and disturbance (*crises gastriques*, described by M. Charcot). M. Krishaber, in a memoir published in the *Gazette Hebdomadaire* in 1880, called attention to a very grave form of ta-

betic laryngismus. The memoir of Cherchevsky, written under the supervision of M. Charcot, contains all the reported cases, and demonstrates the subordination of the accidents to the spinal disease (*Revue de Médecine*, Juillet, 1881.)

More recently, several new observations have appeared in the journals, by Lizé (*Union Médicale*, 21 Juillet, 1881,) by Vulpian (*Rev. de Méd.*, No. 2, 1882,) and by Demange (*eod. loco*, No. 3); all are instructive, particularly the last at a pathological point of view.

Finally, M. Fournier, in his work on *tabes dorsalis* of syphilitic origin, devotes several pages to laryngeal accidents, furnishing the most precise clinical study which we possess of the laryngeal symptoms of locomotor ataxy.

Although the laryngeal manifestations assume very dissimilar forms and other symptoms complicate the clinical tableau, still they may be reduced, according to MM. Fournier and Cherchevsky, to three principal types of varying intensity, from a slight cough to a most formidable attack of laryngismus.

The slight attack is characterized by a peculiar cough, of a spasmodic nature, even in its most attenuated form. The patient has a tickling sensation in the throat, followed by a dry, nervous, irritating cough, which lasts several minutes and then suddenly ceases. The spasmodic element is often very marked in such cases; repeated expiratory efforts occur, a sort of convulsive hiccough, followed by a prolonged and harsh inspiration; a species of attack which has been very aptly compared to that observed in whooping-cough.

In the second type, the sudden perturbation of the respiratory functions predominates. The patient is suddenly seized with extreme dyspnoea; he feels that he is choking, and the face becomes cyanosed. The anguish is extreme, but lasts but a few minutes, for finally the rhythm of the respiration becomes re-established.

Finally, in the most serious form, respiration is completely suspended, and the patient suddenly falls into a state of complete apnoea.

It presents the same clinical tableau as spasm of the glottis, which comes on so suddenly in young infants and so frequently proves fatal.

Such are the laryngeal phenomena; but as may well be imagined, in the more serious forms, the great functions of the organism do not remain unaffected.

There may occur other accidents which relegate the laryngeal symptoms to a secondary position, from simple vertigo and nausea to syncope and epileptoid or apoplectiform attacks.

It is for this reason that Lecoq, in his memoir on the apoplectiform accidents of *tabes dorsalis*, makes a special group of these cases, in which the laryngeal spasms, by the passive cerebro-spinal congestion which they induce, seem to have a predominant part in the causation of the apoplectiform seizure. These sudden attacks are not ordinarily preceded by any precursory symptoms, but sometimes a sensation of tickling is experienced about the larynx, resembling somewhat the aura preceding epileptic seizures.

These laryngeal spasms may have a fatal termination, (Duclos, Jean, Lizé,) either by sudden death, as in the thymic asthma of the newly-born, or by slowly progressing asphyxia.

M. Krishaber has reported such a case, where tracheotomy was required to arrest the progress of the asphyxia.

But, in the great proportion of cases, the spasm is suddenly arrested without leaving any traces after it, no matter what the gravity of the attack, proving that these disorders are purely functional. The duration of the attack is variable, from a few seconds to a few minutes, or even to twenty minutes, in attacks of moderate intensity.

Between the attacks the patients may present symptoms of disorder of the respiratory functions, just as in the intervals between the gastric attacks the digestive functions are in their normal condition.

The laryngeal phenomena have thus, like all the visceral manifestations of locomotor ataxy, a distinctly intermittent character.

Sometimes they occur as often as fifty times in the same day, without any appreciable cause, or under the influence of some passing emotion or vocal fatigue. Sometimes these attacks reappear only after ten or fifteen days; they may even disappear definitely. Certain patients have during the entire course of the disease but one or two attacks, either slight or violent, while others are at any time liable to be stricken down; but it will generally be found that in such cases extensive lesions of the bulb exist, and that by the side of these phenomena, other accidents occur, affecting organs similarly innervated.

No special absolute laws can be laid down regarding the frequency or progressive gravity of the attacks. According to M. Fournier, "The laryngeal attacks augment in frequency and intensity, progressively from their first appearance;" while M. Vulpian expresses a diametrically opposite opinion: "In all the cases I have observed the attacks have gradually become less frequent, less marked in intensity, and have finally com-

pletely disappeared." And in the collection of published cases, facts are found in support of these two contradictory opinions. In fact, is not such the case for almost all the manifestations of tabes?

The period of the malady at which these laryngeal accidents appear, is no less variable than their clinical physiognomy or their mode of evolution. They may appear at any period of the malady, but statistics would seem to show, that in about one-half the recorded cases they appear at the début of the affection. Often months and even years pass by before the other habitual symptoms of ataxy appear. It is very probable that the cases of laryngismus, premonitory of tabes, are much more numerous than medical literature would seem to indicate. Is it not, in effect, possible that such phenomena, particularly when of no very severe nature, are passed over or attributed to one of the many common affections of the respiratory functions?

In other cases, on the contrary, the laryngeal accidents appear late in the malady, and are then but slight and attract little attention. But it is in just such cases that they often prove of the greatest gravity.

We will say a few words in conclusion regarding the pathologic physiology and anatomy of this syndrome. For this we have but three observations with autopsy, (Cruveilhier, Jean, Demange,) and only the two last are complete.

The nature of the laryngeal accidents would seem to point to a functional derangement or an organic alteration of the bulb and of the nerves which thence have their origin—the pneumogastric and spinal.

Conformably with these anticipations, not only bulbar lesions have been found, but also very distinct alterations in the restiform bodies, and a sclerous degeneration of the sensory nucleus of the mixed nerves.

On the other hand, M. Krishaber has shown that these are purely spasmodic phenomena. Their sudden appearance and the negative results of laryngoscopic examination in many cases, are proofs of the truth of this assertion.

It is true that, in certain cases, a paralytic or paretic condition of certain muscles of the vocal cord has been noted; but as has been remarked by this author, "the persistent paralysis of a muscle or group of muscles induces with great facility the spasmodic contraction of its antagonist muscle."

The complete laryngeal attack may then be reduced to a reflex spasm, the genesis of which is explained by the hyperexcitability of the bulb,

and the hyperæsthesia of the laryngeal mucous membrane, receiving its innervation from the pneumogastric.

If such be the mechanism of the laryngeal accidents in tabes, similar manifestations should be observed in the different morbid processes having their localization in the bulb, and these accidents would no longer have any great importance as regards diagnosis.

It is well known that laryngismus is sometimes met in hysterical patients. It has even occurred in individuals in perfect health.

As a premonitory symptom, these laryngeal accidents should be ranged among the possible signs of tabes, and may aid in arriving at a diagnosis; occurring late in the disease, they indicate a grave prognosis, in the sense that they reveal a functional derangement or an organic alteration of the bulb.

COMMUNICATIONS.

SOME PRACTICAL FACTS RELATING TO THE TRANCE STATE IN INEBRIETY.

BY T. D. CROTHERS, M. D.,
Supt. of Walnut Lodge, Hartford, Conn.

In 1877 my attention was called to an inebriate who while sober had purchased a trotting horse, paying a fabulous price, giving a note of hand in part payment. Two days after, he denied all knowledge of the transaction, and became involved in a legal contest. On the trial it appeared that the purchase of the horse had been discussed for a day or more, and that he had exhibited unusual sagacity and judgment to avoid deception and protect himself. Also that, although drinking large quantities of spirits, he gave no evidence of other than good judgment, and perfect knowledge of his acts and their consequences.

In the defense it was shown that the purchase of the horse was a most unusual act; that he rarely ever visited the race course; was afraid of driving fast horses; never took any interest in racing; had many horses of his own; and lastly, needed the money paid for this horse for another purpose which had been determined before. From his own statement he had many blanks of memory while drinking, and at this time he lost all recollection of passing events from the hour of dinner, during which he drank freely, until the second day after, when he awoke in his store, and supposed he had been asleep a short time. His family were sure that in these blank states they could recognize a dullness of mental action and a

general abstractedness of manner not common when sober. He could not read in this state, and seemed incapable of fixing attention on the conversation for only a few moments at a time.

The suit went against him, and soon after he came to the asylum for treatment. His inebriety grew out of inheritance, overwork, and bad nutrition, and was noted for periods of continuous drinking and free intervals of sobriety, both of which were irregular, and not prominent in any particular.

From inquiry I was surprised to find that these blank states were not uncommon among inebriates; that nearly every case gave a history of loss of memory and consciousness of acts committed while using spirits to excess. In some cases, this blank was total and remained so ever after; in others it was partial and cleared up after recovery. Acts committed during the delirium of intoxication, or in mental states approaching this, or stupor, would not be remembered, for some time after, but would gradually be recalled until it was all clear. In other cases this blank of memory would remain like a cloud for weeks, then all at once, from some little circumstance, break away, and every act be perfectly clear.

These freaks of memory (so called), following excess of alcohol, are almost infinite in variety and complexity, and are very significant when studied carefully. Where the blank is total, and remains so, during which the person acts more or less rationally, and never after is able to recall any recollection of it, it is called a trance state. In all probability this is a suspension or paralysis of certain brain functions, or as Dr. Beard believes, a consciousness that is not rememberable. In other words, the person in this state acts as if he was in full possession of all his brain powers, and yet the memory does not record it for future consideration. He is for the time being an automaton—acts and apparently reasons from some unknown stand-point.

Whatever the pathology may be, it is clear that the mind in this state is a mental waif, subject to every passing influence, both from disordered states within and without.

From my experience this state is very common in inebriety, and closely associated with many of the criminal and insane acts committed at this time.

As in all other new phases of science, there is a psychological element, which must be understood before its mysteries can be cleared away. Take any case of a chronic inebriate seen on the streets, and study the operations of his mind and

the nature of his actions, while under the influence of alcohol, and this element will be clear.

The inebriate suffering from excess of alcohol has always a disorganized brain power; various governing centres are suspended, mental and physical incoördination is present, and he is literally unsound, insane, and irresponsible.

If the trance state is present, he is a dangerous automaton, moving along certain fixed lines of conduct, or acting in obedience to unknown forces which may change or vary any moment.

Thoughts and impulses suggested by deranged organs, or coming from the past, may suddenly concentrate into action, irrespective of consequences. Both subjective and objective states, influenced by conditions of health and brain power, may develop into deeds that are practically unknown and unrecorded by the higher brain centres.

The strange unaccountable acts of inebriates who are not stupid or wildly delirious, have been attributed to vice and low moral conditions. Yet a study of these cases reveals an absence of purpose and motive, and a class of actions that are devoid of all sense and common reason. For instance, a man who was an inebriate, while drinking and apparently conscious, sold out his farm at a very low rate. He had no recollection of this event, and there was no reason or motive for doing it. In one case a man forged a note and drew the money on it, while drinking, without any object or motive. He had no recollection of this, and had money at his command, and no possible use for other funds. In another instance, a man in this State offered violence to his father and mother, and was thoroughly unconscious of what he had done. These cases can be multiplied to almost an indefinite extent; and beside having no recollection of the act, they are marked by an absence of all reason or purpose, that indicates their real nature. They are not alone confined to cases of inebriety, but are seen following blows on the head and shocks from traumatism, either physical or psychical. The following cases are marked instances: A leading physician was rendered insensible by injury from a railroad accident: he recovered, went about assisting the wounded, was finally sent home, and regained consciousness, or apparently woke up, thirty-six hours after, having not the slightest recollection of anything which had happened from the time of the accident, in which he was precipitated to the bottom of the car.

A surgeon in one of the large cities was thrown out of a carriage, striking on his head, and was

unconscious for a few moments, got up and went to a hospital, wrote many prescriptions, directing the surgical dressing in several cases, came home and laid down sleeping and drowsy for twelve hours, then awoke, having no recollection of all the time from the moment of the accident.

In these cases there was a trance state following the injury, although there were no signs of this in the manner or actions of the persons. In inebriety such cases are those in which the mind moves along accustomed lines of thought and action, following some plan which has been usual or common in the past.

Epilepsy, insanity, or the emotions powerfully excited, may be, and often are, followed by these automatic phenomena. Instances of such cases are to be found in all medical literature relating to mental diseases, although not recognized by this name or understood. In inebriety there is a peculiar disposition to develop this form of mental disturbance, and its full recognition will mark an era in the progress of science. It is always found associated with a peculiar neurotic condition, either induced by alcohol or existing before alcohol is used. It is also seen most frequently in chronic stages. The practical facts which should be noted are not only to determine the presence of inebriety in a given case, but to study the character and nature of the mental state, and the actions which result from it. No one who uses alcohol to excess can be of sound mind. There are always instability and perversion of mental activity, as well as defective brain power.

The higher brain centres governing the relations of life are disorganized, and morbid impulses of any kind are likely to take possession and guide mental activity. No one can draw dividing lines where normal reason is lost in cloudy, unstable action.

When the inebriate, by his manner and conduct, exhibits manifest hallucinations, delirium, and unnatural stupor or excitement, it is not difficult to recognize the mental disturbance. But when his actions and manner are along the line of natural, every-day life, although he may be using alcohol to excess, and claims to have no recollection of what he has been doing, the case should receive the closest scrutiny.

When a drinking man, not stupid or delirious from alcohol, but known to be using it all the time, commits an extraordinary or unusual act, not in accordance with any reasonable motive or purpose, and after denies all recollection of what he did, the possibility of a trance state is very strong.

It has been well established that inebriates have, through some motive of their own, or by the persuasion of others, deliberately used alcohol for the purpose of giving them some power to commit crime; also hoping by this means to shield themselves from the legal consequences of their acts.

These cases are marked by either an unreasonable frenzy or a cool deliberation that is foreign to the man in his natural condition. The following case was very prominently discussed a few years ago. A mild, quiet man, who was a continuous drinker, and had never been known to do a violent act, committed a most aggravated murder of a man, who was on the best of terms with him, and for no visible purpose. He denied all knowledge of the act, and died in prison before his execution, from consumption following excessive grief. Some years after it appeared that after drinking a certain amount he was unconscious of the nature of his acts, but could be influenced by any strong will, and had been often persuaded to do certain things that were not natural in his sober moments.

It also came out that this murder was planned and urged by two men, who were fully aware of his condition of oblivion to the nature and consequences of his acts; that by continually plying him with spirits, and urging this act, it became impressed on his cloudy brain, and was carried out. This was a condition of trance, which had been noticed and was taken advantage of by the real perpetrators of the crime. I am convinced that much of the purposeless crime committed by inebriates, which puzzles both courts and juries to explain on any reasonable basis of human conduct, originates in the trance state. Such cases are never studied, and are unknown, and the legal efforts to remedy them by punishment literally precipitate them lower, and make recovery more and more difficult.

In an article "On the Trance State in Inebriety," read before the New York Medico-Legal Society last year, I have detailed some very significant cases showing the necessity of careful study of all these cases, by competent men before the nature of responsibility in any case can be determined. The plea of no recollection or memory of the act or event urged by the inebriate is always a physiological and psychological possibility, which can only be settled by a careful study.

So far my studies have indicated that the trance state in inebriates is marked by two forms of mental action that can be determined clearly; one in which the mind in this state moves along certain

familiar lines of action and follows some purpose which has been previously fixed, all of which appears natural and reasonable. The second form is where a new line of thought and action appears, unusual and foreign to his every-day life—often impulsive, inconsistent, and yet seemingly one which he is fully conscious of, and if questioned at the time, may give reasons that seem to justify his conduct.

In both of these forms, sudden changes may occur. Emotional disturbances may precede this state, or appear coincidently with it. The senses are dulled and enfeebled, or intensified in certain directions, and impulses of any character may appear without premonition, like a flash of light, and disappear the next moment.

Every physician should be able to recognize these states, and study their meaning both medicolegally and physiologically. In all probability medical interference in cases of supposed trance, in the form of an emetic or cathartic, or in the shape of a counter-irritant, would restore the normal recognition of environment, and save the patient untold suffering. The subject of inebriety must be studied above the dogmas of theologians and reformers, from the standpoint of science. It is purely a medical subject, and theories based on any other study are always "confusion worse confounded."

AN EXPERIENCE IN THE REMOVAL OF TAPE-WORMS.

BY DR. S. M. WARD,
Of Ellenville, N. Y.

The experience began in this way: One day last summer a gentleman entered my office, and with a mysterious air handed me a small piece of paper, requesting me to open it and tell him the nature of the contents and their source. I will confess that his question somewhat staggered me, for within I found three small white objects, each about an eighth of an inch in length, probably a line in width and thickness, and presenting movements tending to bring their two extremities together, and then straighten themselves again. *There certainly was no resemblance to any segments of tænia soleum I had ever seen.* Using a pocket magnifier, my olfactory organs were brought closer to them, and I detected a slight fecal odor. On the strength of this, I told him they were links of a tape-worm. He was greatly amused at this, and soon after departed without saying more. The more I looked over the specimen and thought of the case, the more I became convinced that my diagnosis was correct. About six weeks afterward

he met me on the street, and said he had concluded that I was right, as another physician had given the same opinion, and vainly essayed its removal with oil of turpentine and castor oil. He requested me to prescribe for him. I then questioned him as to his appetite, pain in stomach or bowels, dizziness, headache, or loss of flesh. Could find out nothing save that occasionally he was dizzy. I saw no more of this patient till some time afterwards. In a few days a manufacturer of a neighboring village who had been under treatment for a stomach difficulty showed me some specimens very like those I had lately examined, and asked my opinion concerning them. I diagnosed tape-worm, and I found out afterwards that he had held a consultation with the first gentleman that had seen me, and both had concluded that they had tape-worms. Case No. 2 was anxious to begin treatment at once, and accordingly was given the following treatment:

Eat nothing for twenty-four hours, take a purge, and in an hour the following:

R.	Ext. kousso, fl.,	
	Ext. filicis mas. fl.,	āā f. ʒj.
M.		

I obtained no results beside a sick and disgusted patient. Several days thereafter he was again treated as follows: He fasted for twenty-four hours and then, having boiled two ounces of fresh pomegranate bark in a quart of water to a pint, took the quantity during a period of four hours, followed by a cathartic. He was overjoyed a few hours thereafter at passing ten feet of worm. I was not so much pleased, as I could discover no head. Accidentally I came across an advertisement of Dundas Dick & Co.'s capsules of male fern and kameela, and determined to try them. Following their directions, my patient ate no solid food for forty-eight hours, and then took three cath. pills M. S. P.; the next morning he took eight capsules, each containing five grains of ext. male fern, and five grains ext. kameela U. S. P.; in a half hour he took seven more, accompanying this last dose with three pills as before. In an hour afterwards he began passing segments of the worm, and altogether delivered himself of sixteen more feet of the animal. I could not feel certain, however, that the head had yet come, as his discharges had not been carefully watched. He was anxious for another trial immediately, and against my better judgment he was allowed to take fifteen more of the capsules. Beyond suffering from violent emeto-catharsis, there were no results.

In the meantime, the first gentleman who had consulted me, hearing of what he considered my

success in the other case, decided to undergo treatment. He was given the same number of capsules in the same way, the only difference being that he took a tablespoonful of castor oil before and after them. His bowels began acting while he was in his stables, and thinking it hardly possible that the medicine could begin acting so soon, he allowed the discharges to become mixed up with a lot of refuse, and I could not determine whether or no the head had come. There were about twenty feet of worm, however, and the patient has passed no more segments while at stool, though the treatment ended some months ago.

CASE 1 was not yet satisfied, and so after some weeks he indulged himself in some more capsules, and again brought forth a number of feet of the worm, with the head. He believes that the success attending this last effort was due to his taking castor oil instead of pills after and before the capsules. His great repugnance to oil is my excuse for not giving it at the other trials.

CASE 3.—A local politician had been treated by many different physicians, including a homeopathist, for dyspepsia, gastric catarrh, etc., without relief, for a number of years. He had concluded that his ailment, whatever it was, was beyond the reach of medical skill, and had decided to forego further medication. Lately, however, he had begun passing "pieces of white stuff" while at stool, and it was to get some light on this matter that he consulted me. I, of course, diagnosed tape-worm, and treated him with the capsules, as in the previous cases. He passed some twelve feet of worm two days after beginning treatment, but no head being found in a week, was put on the same treatment, with the result of passing the head with two or three segments. Of the three cases, this man was the only one who presented subjective symptoms of his complaint. He had dizziness, capricious appetite, irregular bowels, darting pains in stomach and bowels, and though he had not lost any in body-weight, still presented a sickly appearance.

CASE 4.—A workman in a knife factory, suffering from fibroid phthisis. He too had complained of shooting pains in the lower part of his lungs and abdomen, but physical signs of pleuritis being present, they had received little attention; his appetite was excellent—too good, it always seemed to me, for a man in his physical condition. He also gave a history of raw beef eating. He likewise had been passing segments of worm, which served to frighten him severely. I determined that I would lessen the preparatory treatment in

his case, and so, having seen him Saturday afternoon, I told him to eat no supper, and on retiring to take a tablespoonful of castor oil, to eat no breakfast Sunday, and after the oil had operated, to take eight capsules, to wait a half hour, and then to take the remaining seven, with the same quantity of oil. His bowels moved at midnight on Saturday, and he therefore took the capsules early Sunday morning, following the directions minutely. Called Sunday p. m., about four o'clock, and found nearly twenty-five feet of worm, with an undoubted head. Tuesday he resumed work, thoroughly satisfied with his experience.

Were the question asked me if I thought it possible to diagnose the presence of *tænia* without a knowledge that segments had been passed, I should be inclined towards a negative reply. It is true that a history of raw meat eating, dizziness and vertigo, pains in stomach and bowels, and an enormous appetite, with no great tendency to lay on flesh, might point to such as an explanation; but since my four cases, I have been applied to by a man presenting nearly all of these symptoms—dizziness and ringing in the ears being very prominent—in whom there was no history of syphilis, or of an injury, and yet the above treatment has produced no result save making him nauseated. I may add, too, that Case 3 had been told positively by a noted physician of this State that he had nothing like a tape-worm. Of course I should not have looked for it, had I not seen some of the segments he had voided.

I may add in conclusion that all of the worms seemed to be specimens of *tænia medio-canellata* (Küchenmeister).

A REPORT OF A CASE OF COCCYGODYNIA WITH EXTIRPATION OF THE COCCYX.

BY MARIE B. WERNER, M. D.

Read before the Northern Medical Association of Philadelphia.

Mrs. A. came to my office expecting to find relief from an intolerable backache by the introduction of a uterine supporter. A careful digital examination revealed no uterine displacement, prolapsus of vaginal walls or uterus, the latter being, perhaps, possible, since the perineum had been ruptured during her last confinement. The uterine cavity was normal in length. The patient pleaded, however, so strongly for a supporter, that I advised her to remain a few days at my house, until I could obtain one which might give her the desired relief; trusting that during that time I might find the cause of her suffering.

I soon observed that this pain was aggravated

in the act of sitting down or reassuming the erect position, and the idea occurred to me that the pain might be due to some other than uterine trouble. I therefore requested to make another examination, and found the origin of the trouble was at the extremity of the coccyx, which was turned to the right and painful on pressure, as also that portion of the left sciatic ligament, which was thickened at its attachment to the coccyx. Her history showed that she had suffered this pain about one and a half years (since her confinement), and increasing as time advanced—more since she had suffered a severe abdominal inflammation during the previous winter.

Drs. Montgomery, Croasdale, and Hunt, examined the patient under the influence of ether, and arrived at the same conclusion.

There seemed no other means to afford relief than by operation, a choice of two presenting—one being a subcutaneous division of all attachments, the other, extirpation of the bone.

The patient was satisfied to have either one or the other done, as should be deemed best at the time of operating.

To me it seemed no small matter to remove a portion of the spinal column, even if it was its extreme end, especially since the authors within my reach were not very clear as to the manner of operating, while some did not even seem to favor operative interference. It was only some time after that I had the pleasure of reading Simpson on "Diseases of Women," who, among authors on this subject, seemed to me the most clear.

The patient was etherized on June 13, in the presence of Drs. Montgomery, Croasdale, Barton, and Hunt; a subcutaneous incision made, severing all the attachments to the coccyx, which seemed, however, to promise no permanent restoration in its position; hence, it was decided to remove it entirely, there being a possibility of abnormal adhesions forming again, with an almost certain return of the distressing symptoms.

An incision was made in the median line down to the coccyx, about three inches long, the bone dissected out, but well forward, and disarticulated at its junction with the sacrum; the finger of the left hand being constantly kept in the rectum. The wound was closed by means of three silver wire sutures, introduced with the Baker-Brown needle, and imbedded their entire length, thus closing thoroughly the pocket left by the removal of the bone. It was dressed with carbolized lint compress and bandage. 6 p. m., temperature 99.6°, pulse 90; no nausea; complains of some

pain at seat of operation, which was relieved after the compress and bandage were removed.

14th, a. m. Temperature 99°; pulse 80. Patient rested well during the night, not much pain; the old ache in the back has not been felt since the operation. P. M., temperature 99°, pulse 86.

15th, a. m. Temperature 98.8°, pulse 80. Patient rested well during the night; complains of some pain when urinating, for which was ordered flaxseed tea and bicarbonate of soda. P. M. Temperature 98.8°, pulse 84. The pain on micturating has abated somewhat; some stinging pains at seat of operation; on examining, found the wires had excoriated the skin somewhat: there was, however, no redness or swelling, and to all appearances union by first intention.

16th, a. m. Temperature 99°, pulse 86. Patient did not sleep well, owing to a constant desire but inability to urinate. I withdrew by catheter one-half gill of urine dark in color. This tenesmus was again diminished by the free use of the flaxseed. P. M. Temperature 98.8°, pulse 80. Patient was extremely restless, moaning during the entire night, complaining of pain at the site of the wound, and extending up the back. She described it of a throbbing, stinging, and cutting character. Nothing could be detected beside the excoriations, as the cause of it; union seemed complete. Repeated doses of morph. sulph., until one grain had been taken, seemed to have no effect in affording relief. On the following morning I removed the stitches in the presence of Dr. Croasdale and Dr. Montgomery. A cessation of that terrible pain followed.

The patient made a good recovery; the urinary trouble abated as she could move about in a less restrained manner. There was for some four or six weeks still some soreness felt after continued sitting, which I attributed to the newly-formed periosteum; but this gradually became less, until now she feels nothing of the old pain, and her general health is greatly improved. The extirpated bone showed that its free extremity was the seat of a beginning osteitis.

A recent examination showed that that portion of the sciatic ligament involved is less thickened, but still somewhat tender, the patient being not aware of its soreness until it is touched.

—The first operation for the relief of club-foot by division of the tendo achillis, was performed by Lorenz, of Frankfort, on the 26th of March, 1782. Dr. David L. Rogers, of New York city, was the first to perform tenotomy in this country, in 1834.

HOSPITAL REPORTS.

A CLINICAL LECTURE.

BY FRANCIS DELAFIELD, M. D.,

Adjunct Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons, New York.

GENTLEMEN: The history which this man gives is a very common one. It is the history of a condition which we find in a great many persons, both of men and women, many of whom have this man's general appearance. The man tells us that he was fairly well, except for some constipation of the bowels, until last September. At that time he was at work in some one of the peach orchards, and ate considerable fruit; so much so that his bowels became unnaturally loose at that time, but ever since then they have been constipated, and this persistent constipation is now accompanied with another symptom, namely, a peculiar sensation about the head, a feeling which he describes as both a fullness and a dizziness, and a partial loss of memory. He has used these three expressions—fullness, dizziness, and loss of memory—to describe the feeling. The dizziness has never been so great as actually to cause him to fall. Such are the rational symptoms.

On making physical examination we find that the heart is a little enlarged; there is a distinct murmur heard with the first sound over the apex. The murmur can be heard distinctly over the apex, but it is not transmitted to the left with any great distinctness. It is lost in the axilla.

On looking at the abdomen, we see at once that the man is not at all emaciated, and the contour of the abdomen is regular enough. As the man lies down the liver hardly reaches to the free border of the ribs, while the upper edge of the liver is about where it ought to be, namely, between the fourth and fifth ribs, so that the organ is rather small for a man of his size. The spleen seems to have about its natural outlines. There is a little distension of the large intestine, and there is a certain amount of gurgling over the caput coli and the descending colon, which ought not to be present.

That constitutes the physical examination—that the man's heart is slightly hypertrophied, that there is a systolic murmur at the apex which indicates a regurgitation at the mitral valve; the liver is a little diminished in size; the abdomen is rather full; the large intestine is somewhat larger than it should be, containing rather more fecal matter mixed with fluid than it should.

If we put together the man's history and the results of the physical examination, what should be our diagnosis? The man has some heart trouble, but it is very slight, and I should judge that it had nothing whatever to do with his present symptoms. Then the question arises, what is the connection, if there is any, between the constipation and the cerebral symptoms? I should say that this connection was a direct one; that the man has cerebral symptoms on account of constipation; and that if he gets rid of the constipation, the cerebral symptoms will also cease. With the sort of cerebral symptoms which he complains of, that is, fulness about the head, dizziness, and loss of memory, we often find a

variety of disturbances of the digestive tract. Such cerebral symptoms are found with disturbance of the stomach, of the liver, and of the intestine, and they are common enough; but the point is to find out just what part of the intestinal tract gives rise to them. In this man's case I should think the relation could be traced with considerable certainty, viz., that the cerebral symptoms are dependent directly upon constipation; and constipation, in this case, is evidently due to disturbance of the functions of the large intestine. Apparently the stomach and the small intestine are performing their functions fairly enough. The patient gives no symptoms of gastric dyspepsia, he is fairly nourished, so that the food must be absorbed from the small intestine in sufficient quantity.

The particular function of the large intestine which is interfered with, is that which is concerned in the expulsion of the fecal matters. The fecal matters form, apparently, and accumulate in the large intestine. There is a fair amount of them in the large intestine at the present moment, but the gut apparently is not able to expel them.

This brings us to the question of treatment, for that is really the practical point in this man's case. It is evident that the indication for treatment is to remedy the constipation. But constipation can be removed in a great many ways, and the particular way which is to be of service to an individual will vary very much in different cases. Now, if any of you were brought face to face with a case like this, with such a history, there being constipation which had been extreme only for a moderate length of time, and if you thought, as I do in this case, that the symptoms all depended upon the constipation, what would you do to relieve the patient? "Give him small doses of aloes?" That would be a thing easy enough to do. But what would be your object in giving aloes? "It has a direct effect upon the large intestine, increasing its peristaltic action." Very well, we will suppose that aloes would be of use for that particular purpose. Can some one suggest something else which would be of benefit in this man's case? "The extract of *nux vomica*." Yes, or with the same idea, small doses of strychnia; that is, to be given with the idea that it would act directly upon the muscular coat of the large intestine. You could make a combination of these two drugs, and give them together, which would produce a result more efficacious than if but one were given. Now, you could give this combination of aloes and strychnia in one of two ways; you could give it in moderate doses at night, or you could give smaller doses three times a day. By a moderate dose, I should say for this man a twentieth of a grain of strychnia and one grain of aloes, to be given at night. This would very likely produce a movement of the bowels the next morning. For a small dose I would give him only a fortieth of a grain of strychnia and a fourth of a grain of aloes, to be taken three times a day. Sometimes the one, sometimes the other of these plans is the better for the administration of these medicines.

Although in a case like this the afore-mentioned drugs would be indicated theoretically, yet, as a matter of fact, with this particular man, and with his history and condition, they are not the

drugs which I should be disposed to choose. These drugs, compounded in this way, are of very great service for many cases of constipation of older people. Yet in this man's case I should be disposed at least to try the following :

R	Ext. belladon.,	gr. $\frac{1}{10}$.
	Pulv. ipecac,	gr. $\frac{1}{4}$.
	Ext. colocynth. co.,	gr. j.

To be taken in pill form every night on going to bed. That you will notice is not a strong dose, and yet it will probably cause a movement on the next day during the time that he continues to take it. After having once begun this course of treatment, the question will arise, when can you safely leave off giving the pills? And that is often the most difficult point regarding treatment in these cases. It is often easy enough to give these patients something which will relieve them of their present state of constipation, but we do not want that they should have to go on taking pills the rest of their lives. Now, in the first place, the patient must not be in too much of a hurry to get rid of the necessity for taking the medicine. You do not only want to get the bowels to working regularly, but also into the habit of working readily. There is a good deal in the force of habit so far as the large intestine is concerned, and it is important to induce the patient to have a regular movement at a particular time every day for a considerable length of time. Sometimes it will require several months before you can cease to give the medicine, and it is then best not to give it up altogether immediately, but to diminish the quantity. Allow the patient to take a third less than he had been taking, then a half—and so diminish the amount by degrees, and by-and-by you can cease to give any medicine at all, and yet the bowels will continue to act freely.

As you do this, however, you have to pay attention to the diet, and observe whether the patient will bear fruit, oatmeal, and the porridges of different kinds, which are of service in loosening the bowels. The regulation of the food is not of as much consequence at the beginning of the treatment as it is in the later periods, when you are trying to get rid of the necessity for giving the drug.

CASE 2.—This patient, aged twenty-eight years, says he has been unwell for a year past. The three prominent symptoms of which he complains are, a want of strength, inability to sleep, and an irritable condition of the heart. He also complains of some pain in the stomach, which is a matter of some consequence, but it is not so important as are the other symptoms. We find that his heart is beating at the rate of 120 per minute, but there is no murmur. He says he has lost about thirty pounds of flesh within the past year, but he is still very well nourished indeed. His business has been that of bar-tending. He says he drinks very little, but that he smokes eight or ten cigars a day.

Now, if a man were to present himself to you, complaining of the symptoms which this man complains of, and he should tell you that his business was that of a bar-tender, you would probably infer at once that his symptoms were due to his mode of life, and that they would disappear with a change in his mode of life. But this patient has quit bar-tending, has changed his mode of

life, and yet he has not gotten better; and that is what happens in a good many such cases. The first part of your inference would probably be correct enough, to imagine that the man's symptoms were due to his mode of life, that they were very largely due to the effects of tobacco upon him, and a derangement of the stomach which probably, in this case, has resulted from his manner of living. But you will often find that on changing the patient's mode of life, he not only may not get better, but may actually go on to get worse. Finding, on taking your advice to stop his occupation for some months, that he does not get better, the patient will probably infer that you knew nothing about his case. Still, you had taken the right view of it, but you made a mistake in supposing that simply stopping his mode of life would put an end to his trouble.

This brings us to the practical point, as to what we can do for a patient in this condition. This man has given up his occupation as bar-keeper, and is now doing nothing. He has felt so weak that he has spent a good deal of the time in the house, only going out from time to time to take a walk. There, in the first place, is something which should be looked after. The man ought to have some occupation. He is leading an unhealthy life at present. A man of his build has no business to be unoccupied. He ought to be out of doors. His muscles need exercise. He would be better off, I think, really, to follow his old occupation as bar-keeper, than to do nothing at all. But it would probably be better for him if he could find some out-door business—something that would keep him moving about from place to place, or require work. Should he continue his old occupation, he probably could get more out-door exercise in connection with it living in the West than while living in New York. The tobacco, which he has already given up, he will have to continue to do without. He can not return to that, not even in the smallest quantity.

Then, the man wants to be relieved of the pain in the stomach, and of sleeplessness. Could he be relieved of those two symptoms, he would probably begin to feel better very soon. The pain in the stomach is a sensation of burning, unaccompanied by vomiting. The appetite is fair. He says he has been taking iron and quinine. I should suppose that the man would really be better without these two drugs than with them. The bicarbonate of soda, which he has already been taking, may be continued, and to it I should add quassia and the oxalate of cerium, to be taken regularly before each meal.

The first drug which I should try in his case to induce sleep would be hyoscyamus, and for this purpose I should use the concentrated tincture, made by Kieth & Co., of this city, in from ten to twenty or forty drops; twenty drops is the average dose. It should be diluted in about eight parts of water. If, after taking this at bed-time for several nights, sleep was not induced, I should increase the dose from twenty drops to thirty, and then to forty. If the man were still unable to sleep, I should combine the fluid extract of convallaria with the hyoscyamus, with the object of quieting the irregular heart action. A common reason for the inability on the part of these patients to sleep seems to be a too rapid heart-beat,

and it is sometimes found that a combination of these two drugs will bring about sleep when hyoscyamus will not do so alone. If this combination did not prove successful, I should use one of the bromides and chloral together; the bromide of sodium, of ammonium, or of potassium—one seems to be about as good as the other. Thirty grains of one of these bromides, with twenty grains of chloral hydrate, should be given at night. That might prove a very successful remedy against sleeplessness, just as the hyoscyamus might do, and again it might not have any effect at all. In the case of some patients, instead of making them go to sleep, they are more wakeful; and in others, it has no effect whatever that night, while it may make them very sleepy the next day, and on the following night they may become still more sleepless than before.

Another drug which may be used is opium, and after all this is really a very good drug to relieve sleeplessness in a case like this, and I do not hesitate to use it. Of course, you have always to bear in mind the possibility of establishing the opium habit. But this can be guarded against if you keep the patient under observation, stopping the drug when you think it best to do so. Opium is an exceedingly good therapeutical agent for this purpose. The best preparation of the drug for making these patients sleep is not, I think, usually morphine, although for many purposes this preparation is an excellent one. The deodorized tincture of opium, prepared by Squibb, is a very good preparation for ease like the one before us; so also is codeia.

MEDICAL SOCIETIES.

NORTHERN MEDICAL ASSOCIATION OF PHILADELPHIA.

Meeting of January 26, 1883.

President Dr. J. T. Eskridge in the chair.

Dr. Marie B. Werner read "A Report of a Case of Coccygodynia with Extirpation of the Coccyx." (See page 287.)

Remarks.—Dr. E. E. Montgomery referred to the manner in which Dr. Werner introduced the sutures, and explained that the pocket usually resulting from merely bringing the edges together by the ordinary method of suturing was, by this procedure, completely obliterated, and the consequent healing by granulation overcome.

Dr. L. Brewer Hall desired to be informed whether or not the severance of ligaments and the attachments of adjacent structures, the result of this operation, is followed by misplacements of the uterus. The question is still *sub judice*.

Dr. Daniel Longaker referred to coccygodynia resulting from other causes than luxation of coccyx, and directed attention to the necessity of clearly differentiating between reflex pain and that dependent upon change of relationship of structures. In a case of myo-fibroma uteri, in which coccygodynia was a most distressing symptom, the diminution of the growth was accompanied by a corresponding decrease of pain.

Dr. Henry Beates reported a case of excision of the coccyx, with result of perfect cure of dis-

ease. The lady was greatly reduced in health, having suffered from acute articular rheumatism, which involved the endocardium, and left a regurgitant mitral lesion. Superadded to this was a co-existent rectocele, and a lacerated cervix, which occasioned distressing symptoms. The coccygodynia was of twelve years' standing, and the suffering so intense that threats of self-destruction had often been made. The Doctor performed trachelorrhaphy, and at the same time excised the coccyx. The sutures were not applied as Dr. Werner's method suggests, and as a result the pocket was obliterated by healing by granulation, which required nearly five weeks. The coccyx was luxated from behind forward, with lateral (left) deviation.

Prof. J. B. Walker reported a case of peritonitis that would, in all probability, terminate fatally, which resulted from the use of large hot-water vaginal injections. The injections were used by the patient for the relief of a profuse vaginal discharge, either leucorrhœal or gonorrhœal in nature. The Doctor referred to the caution mentioned by Dr. E. L. Dreer, which is to obliterate the central orifice of the syringe-pipe, in order to prevent the jet being thrown into the uterine cavity.

Dr. E. E. Montgomery is of the opinion that the individual is suffering from an extension of an inflammation, gonorrhœal or not, from the uterus to oviducts, and that the salpingitis is the cause of the peritonitis, and not the hot water.

Dr. Walker spoke of the harmlessness of hot water in the peritoneal cavity, and did not wish to be understood to state that the peritonitis was the result of admission of simple hot water, but due to *pus* entering the peritoneal cavity. The *pus*, he explained, was forced through the oviducts by contraction of the unstriated muscular fibre, and the contraction depended upon the entrance into the uterine cavity of the hot water. Too great care cannot be exercised in the use of simple, and, under ordinary circumstances, harmless injections; and this case, with its probable fatal termination, should serve to impress upon the mind of every practitioner the importance of extreme care in the treatment of similar instances of inflammatory affections of the female genito-urinary tract.

TRANSACTIONS OF THE ATLANTIC COUNTY, N. J., MEDICAL SOCIETY, HELD AT ATLANTIC CITY, ON MONDAY, FEBRUARY 5, 1883.

The President, Dr. Boardman Reed, in the chair.

The minutes of the last regular meeting were adopted as read.

Drs. S. A. S. Jessup, Rebecca Hallowell, H. H. Bennett and Chas. Souders, of Atlantic City, and Dr. Edward North, of Hammonton, were elected members of the Society.

Propositions for membership were received from Drs. William Pollard and J. J. Comfort, of Atlantic City, and Joseph North, jr., of Pleasantville.

A committee was appointed, consisting of Drs. D. B. Ingersoll, Edward North, and J. B. Somers, to take steps towards procuring more stringent laws regulating the practice of medicine, regulating admission to insane asylums, and concerning the payment of expert testimony.

The President and Secretary were appointed a committee to invite an eminent Philadelphia specialist to lecture before the Society at its next regular meeting.

The subject of "Indigenous American Medicines," was chosen for discussion at the next meeting.

An amendment to the By-Laws, inserting the reading of essays and reports of cases in practice as special items in the rules of order, was adopted.

The resignation of Dr. T. P. Waters, who has removed from the county, was received and accepted.

Dr. D. B. Ingersoll described an interesting post-mortem examination which he had recently conducted in connection with Dr. Boardman Reed. The probable cause of death, together with the medico-legal aspects of the cases were variously discussed and commented on by the members present.

Owing to his serious illness, Dr. Willard Wright was unable to be present and present his essay; he was therefore reappointed essayist for the next meeting, with Dr. L. H. Armstrong as his alternate.

After some further discussion of an informal character regarding the meeting of the State Medical Society, which meets in this city in June, the meeting adjourned to meet again on Monday, May 7, 1883.

THEO. H. BOYSEN, M. D.,
Secretary.

PROCEEDINGS OF "THE COLLEGE OF PHYSICIANS OF PHILADELPHIA."

A Partial Study of the Poison of *Heloderma Suspectum* (Cope)--The Gila Monster.

BY S. WEIR-MITCHELL, M. D., AND EDWARD T. REICHERT, M. D.

[Read February 17, 1882.]

(Being the complete paper, an abstract of which appeared in our issue of Feb. 24th.)

For some years past it has been known to naturalists that the Gila lizard of Arizona and Sonora was endowed with anterior deciduous grooved teeth, which communicated by ducts with large glands within the angle of the lower jaw. These arrangements naturally suggested a certain power of poisoning, as to which, however, the most conflicting accounts have reached, and continue to reach us from Arizona. In many houses the sluggish creature shown to you was a pet of children, and seems to have been averse to using his weapons of offence. The occasional accidents from his bite were variously explained away; but still, among the Indians and some settlers, he enjoyed an evil reputation. Only within a week we have had two letters from Arizona, the one describing him as "more peaceful and harmless than a young missionary," and the other as being "worse than a whole apothecary shop." Nevertheless, both in France, and of late in London, specimens have bitten and promptly killed small animals.

It is worth while to mention more distinctly some of the evidence for and against the poisoning power of *Heloderma*. His bad name in Mexico is mentioned by Bocourt and Dumeril, but Sumichrast is more full in his statements.

This curious lizard is, he says, slow and embarrassed in his movements, and hides in the daylight, and especially in dry weather, to emerge at night and in wet seasons. He is said to smell ill, in fact to be of a nauseating odor, and is described as slobbering forth a sticky, whitish saliva when irritated. The natives, says Sumichrast, hold him in the utmost terror, and consider him as more fatal than any serpent. When made to bite a fowl, it died in twelve hours, with bloody fluid exuding from its mouth, the wound being of a purple tint. A cat bitten was very ill, but recovered, remaining thin and weak. The *Heloderma Horridum* sent to London, to Sir John Lubbock, killed a frog in a few minutes, and a guinea-pig in three minutes.

Many years ago, Dr. Irwin, U. S. A. (*Amer. Naturalist*, Nov., 1882), experimented in New Mexico with the Gila monster, and concluded it to be harmless, while Mr. Horan, Superintendent of the National Museum, says he himself has been several times bitten without serious results. The following statement of Dr. Shufeldt (*Amer. Naturalist*, Nov., 1882,) adds a further difficulty in making up our estimate of the powers of *Heloderma*. The lizard he speaks of is the one we now exhibit. It was sent to the Smithsonian Institution by A. T. Burr, U. S. A., and is the *H. suspectum* of Cope.

"On the 18th inst., in the company of Professor Gill, of the Smithsonian Institution, I examined for the first time Dr. Burr's specimen, then in a cage in the herpetological room. It was in capital health, and at first I handled it with great care, holding it in my left hand, examining special parts with my right. At the close of this examination I was about to return the fellow to his temporary quarters, when my left hand slipped slightly, and the now highly-indignant and irritated *Heloderma* made a dart forward and seized my right thumb in his mouth, inflicting a severe lacerated wound, sinking the teeth in his upper maxilla to the very bone. He loosed his hold immediately, and I replaced him in his cage, with far greater haste, perhaps, than I removed him from it.

"By suction with my mouth, I drew not a little blood from the wound, but the bleeding soon ceased entirely, to be followed in a few moments by very severe shooting pains up my arm and down the corresponding side. The severity of these pains was so unexpected that, added to the nervous shock already experienced, no doubt, and a rapid swelling of the parts that now set in, caused me to become so faint as to fall, and Dr. Gill's study was reached with no little difficulty. The action of the skin was greatly increased, and the perspiration flowed profusely. A small quantity of whisky was administered. This is about a fair statement of the immediate symptoms; the same night the pain allowed of no rest, although the hand was kept in ice and laudanum; but the swelling was confined to this member alone, not passing beyond the wrist. Next morning this was considerably reduced, and further reduction was assisted by the use of a lead-water wash.

"In a few days the wound healed kindly, and in all probability will leave no scar; all other symptoms subsided without treatment, beyond

the wearing for forty-eight hours so much of a kid glove as covered the parts involved.

"After the bite our specimen was dull and sluggish, simulating the torpidity of the venomous serpent after it has inflicted its deadly wound, but it soon resumed its usual action and appearance, crawling in rather an awkward manner about its cage."

The specimen shown has eaten once since we have had him, but the Gila monster is said to live on bird eggs, and to eat daily of like food while in captivity.

The sluggish habits ascribed to *Heloderma* in general have been noticed in our specimen; but it is clear from Dr. Shufeldt's accident, that, like the habitually inert *Crotalidæ*, this creature is capable of sudden and therefore, unexpected agility in attack.

As we shall have sent to us in the spring a number of *Helodermas*, we shall then be able to complete the study of the poison of these interesting lizards—the only members of the family of lizards as yet known to be poisonous. The subject is, however, too full of interest to delay the publication of our preliminary study, since, as far as it has gone, it is perfectly definite and satisfactory.

The Gila monster inhabits the dry hillsides of Arizona, and is said to reach the length of three feet.

The specimen we exhibit is about fourteen inches long, and from war or accident, had, when he reached us, lost all but two of his teeth, and as yet no new ones have taken their places. Without them he would certainly be as harmless as a rattlesnake deprived of his fangs; and as these teeth are very small and easily removed, their absence may account for some of the instances in which the lizard has bitten and done no grave harm.

Experiments made in the usual vague way, by allowing the lizard to bite animals, are obviously untrustworthy; so that it was thought best to use the saliva in known quantities. The fluid was obtained by provoking the animal to bite on a saucer-edge—which it was most indisposed to do. When once it had seized the saucer it was hard to pull it away, so powerful was the grip of the lizard's jaws. After a moment, a thin fluid like saliva dripped in small quantities from the lower jaw. It was slightly tinted with blood, due to the violence of the bite, and it had a faint and not unpleasant aromatic odor. The secretion thus collected from the mouth was distinctly alkaline, in contrast to serpent venoms, which are all alike acid.

"*Experiment I.*—About four minims were diluted with one-half cubic centimeter of water, and thrown into the breast muscles of a large, strong pigeon, at 4:23 p. m. In three minutes the pigeon was rocking on its feet, and walking unsteadily. At the same time the respiration became rapid and short, and at the fifth minute feeble. At the sixth minute the bird fell in convulsions, with dilated pupils, and was dead before the end of the seventh minute.

"The first contrast to the effects of venom was shown when the wound made by the hypodermic needle was examined. There was not the least trace of local action, such as is so characteristic of the bite of serpents, and especially of the *Crotalidæ*.

"The muscles and nerves responded perfectly to weak induced currents, and to mechanical stimuli.

"The heart was arrested in the fullest diastole, and was full of firm black clots. The intestines looked congested. The spine was not examined."

EDITORIAL DEPARTMENT.

PERISCOPE.

Tubercle Bacillus and Phthisis.

In the *British Medical Journal*, February 3, 1883, Dr. T. Henry Green (Physician to Charing Cross Hospital, and Senior Assistant-Physician to the Hospital for Consumption and Diseases of the Chest, Brompton), in concluding a lecture on the relation of this micro-organism to phthisis, observes, with regard to treatment: "What is the practical teaching of Koch's discovery with reference to the prevention and cure of phthisis? If our pathological conclusions be even only partially true, they clearly indicate, I think, the necessity of carefully distinguishing between the bacillus and the conditions which favor its influence, and of directing our treatment to both. We must endeavor to prevent the access of the organism, and, if possible, to destroy it after it has effected an entrance; and we must also strive to maintain a healthy condition of the pulmonary tissues, and

thus prevent the occurrence of that tendency to apical stagnation which appears to be such an important, if not essential, factor in the disease. The latter of these indications is, I believe, as important as the former; and it is, perhaps, rather in danger of being lost sight of in the very natural eagerness with which attention is now being directed towards the bacillus.

"Firstly, then, with regard to the condition of the lung which favors the influence of the bacillus. Here it is only necessary to remark that, whatever promotes a vigorous state of health will, by improving the condition of the blood, the nutrition of the vessels, and activity of the circulation, and the exercise of the respiratory function, tend to prevent that stagnation and transudation in the highest portions of the lungs, the etiological importance of which we have so especially insisted upon. The value of treatment which has for its object the fulfilment of these indications in the prevention of phthisis it is, I believe, difficult to over-estimate; and its usefulness is almost,

equally valuable when the disease is established. I cannot but think that, in the meantime, such treatment promises better results than any attempt to attack the specific organisms. Secondly: the tubercle bacillus. The consideration of this naturally divides itself under two heads: (a) the prevention of its access, and (b) attempts to destroy it when the disease is developed. (a) The prevention of the access of the bacillus. The present position of our knowledge appears to point to the desirability of adopting measures for the disinfection and destruction of the sputa of patients suffering from phthisis; and perhaps, also, of the alvine secretions, when there is any evidence of tuberculous disease of the bowel. It also raises the question as to how far it is desirable to allow individuals who are not consumptive, but who inherit a phthisical tendency, and especially when such individuals are out of health, to intimately associate with those who are suffering from the disease. If our pathology continues to move on the same lines, this subject may become one requiring the consideration of those who manage our hospitals. (b) The destruction of the bacillus after the disease is established. Attempts to do this are made principally by means of antiseptic inhalations. This is the fashionable, though perhaps somewhat misdirected, therapeutics of the day. A respirator charged with some antiseptic, such as creasote or carbolic acid, is now being largely used in the treatment of phthisis. Although I should be very sorry to unfairly criticise such treatment, I cannot but think that the evidence that its usefulness is in any way dependent upon its destruction of the bacilli, or of any infective substance which they may originate, is wanting. It seems to me much more probable that such inhalations, when beneficial, are so mainly through the favorable influence which they exercise upon the mucous membrane and secretion; and when, as is often the case, they are combined with chloroform, they will also act as direct sedatives. What we want are cases of early and progressive phthisis in which antiseptic treatment alone, without adjuncts, is followed by marked improvement. When it can be shown, *e. g.*, that the pyrexia of early phthisis is reduced by such treatment, we shall have evidence pointing to the influence of the germicides upon the bacillus, of considerable value. We are now making some observations in this direction, but, at present, with negative results. Whilst, therefore, I do not wish to be understood to discourage the treatment of phthisis by antiseptic inhalations, I think we must be careful as to the interpretation we put on their results. The treatment of phthisis and of other pulmonary diseases by means of medicated atmosphere has been greatly stimulated by Koch's discovery. Such treatment has undoubtedly been too much neglected in the past, and its prosecution promises the best results. But, in the meantime, I think we have no evidence that we are able by such means to influence the tubercle bacillus; although, if Koch's investigations be true, the discovery of some agent which, by destroying it, will arrest its injurious influence, is obviously the greatest desideratum."

—Picric acid is the latest topical application in erysipelas.

A Congenital Anomaly of the Conjunctiva, Hitherto Unreported.

Dr. J. F. Streatfield reports this case in the *Lancet*:

At the Moorfields Eye Hospital, on the 11th of May this year, I saw among others in the crowd of out-patients, a lad who had evidently some conjunctival redness of both eyes, which on examination proved to be nothing but a slight catarrhal ophthalmia. To determine this point, and suspecting it might be a case of granular lids, I looked under the upper lid, and also specially, as usual, to the outer angle of the lower lid on its inner surface. For this purpose I made traction on the skin downwards, and then also somewhat outwards. As I was thus pulling the outer canthus away from the eyeball, and everting the lid, a conjunctival fold came into view, which evidently limited and abbreviated somewhat the normal amount of separation to be effected between the eyelids and the eyeball, the palpebral and ocular conjunctivæ, at this part. Then, with another finger, I also lifted the upper lid at the outer angle, and the fold I had observed came very prominently into view. It extended exactly horizontally from just behind and within the outer canthus, to nearly the outer margin of the cornea. It would not allow the lid to be lifted so far as they may be usually away from the eyeball, but the normal movements of the eyes when the lids were *in situ* were not by it interfered with. Being stretched, by lifting the two lids as I have described, the little straight fold was seen to be semi-transparent, and, seeming to consist only of the folded normal conjunctiva, it reminded me of the little vertical fold of mucous membrane under the tongue of infants to which one's attention is so often directed, when, as their mothers and nurses say or suppose, the child is "tongue-tied." In each palpebral aperture this abnormal frænum existed, and was altogether quite symmetrical. There were no other oculo-palpebral prominent folds, nothing like symblepharon in either eye. The patient knew nothing of the anomaly I am describing; he had had nothing the matter with his eyes but the present insignificant conjunctival inflammation. Symblepharon as a congenital affection has been reported, but the present case cannot possibly, I think, come under this category, because—(1) The conjunctiva was only shortened, or of little extent, directly outwards in either eye, as a little fold forwards and horizontally, instead of a backward and vertical fold. It was not thickened, or otherwise changed in appearance, as are the folds in the reported cases of congenital symblepharon, which seem to have been the result of intra-uterine inflammation, nor did the eyes themselves and the eyelids, excepting as regards these purely conjunctival fræna, show any structural abnormality, any inflammatory results, fetal or otherwise, or any ill-development—if I may assume that these fræna were evidences of ill-development of the conjunctival sacs; because (2) these fræna in my case were only just at the outer angle—*i. e.*, where any symblepharon is not very likely to occur; and also because (3) of the exact symmetry that existed. It was, I think, a partial malformation. I find no notice of any such congenital anomaly in Professor Manz's chapter (vi.) in Graefe and

Saemisch's Handbook, or in other books. These fræna may perhaps be explained by a consideration of the development of the eyelids; an upper, lower, and inner lid are formed, of which the latter, although in the human subject it is quite rudimentary, yet must not now be forgotten, for in the novel and possibly unique case I am recording, the forward folds of conjunctiva were only at the outer canthus and exactly horizontal—that is to say, where without the rudimentary inner third lid, the two greater eyelids come close together into contact, being formed by two, an upper and a lower, infoldings of the integument. If such infoldings above and below, as two pockets, are likely, as I suppose, to leave between the two a tegumentary ridge or outfold, I will venture to guess that I have in the present case found a congenital abnormality not so very rare as hitherto undetected. We constantly open eyelids and look up and down under the two lids, but we do not specially observe if the two lids together are perfectly and normally separable from the eyeball at their junction at the outer angle. Is the common congenital abnormality called epicanthus a (displaced) development of the third eyelid of the lower animals? Is the plica semilunaris in such cases absent? I have not myself observed that it is.

The Lesion of Myo-Carditis.

Dr. James Grey Glover describes in the *Lancet*, January 20, 1883, the case of a man aged fifty, the subject of occasional attacks of emphysema and bronchitis, who was suddenly seized with violent pain in the region of the heart, and alarming syncope. When seen, there was no disturbance of the circulatory system, and having recovered from the attack, he complained only of pain across the diaphragm, and especially to the right side over the liver. In a few days, although feeling weak, he returned to his business. Ten days later, not feeling well, and having pain in the chest, he sent for Dr. G., who saw him in his library, and was just beginning to hear from him an account of his illness, when his head fell back in his chair, and his feet forward, and he died in a few minutes. A friend at whose house he called the night before said he looked ill and "altered," and complained of "a pain at the heart," but said he should soon be better.

Post-mortem Examination.—The body was found very fat, and the muscles well nourished. The cartilages of the ribs were so ossified as to require the use of the saw. There was a good deal of fat about the heart; but no hardening of the coronary arteries. The pericardium contained about an ounce, or less, of fluid. There was an ecchymosis on its inner surface opposite the base of the heart, to the left side in front. There was also a little recent lymph hereabouts. But the marked lesion was on the front of the apex of the heart, affecting, apparently, both the surface and a layer of the substance of this organ. At this spot there was a well-defined roundish patch, less than the size of a five-shilling-piece. It looked badly damaged, and on the road to gangrene or sloughing. In color it was dirty red, with a little dirty lymph about it. The great vessels proceeding from the heart contained decolorized clots of fibrin.

The opposing spot of the pericardium had a corresponding appearance—ecchymosed and with a little dirty lymph on it, but with no adhesion. The valves were unaffected. The lungs were emphysematous and congested, but everywhere free from consolidation. The liver was hard, and its capsule at parts opaque. The kidneys were similarly affected, and had a few small cysts on their surface.

Remarks.—I shall not attempt to trace the course of pathological processes in this painful case, nor assign their exact significance. The fibrinous clots in the large vessels probably had much share in causing death. Possibly some similar clotting may have occurred in the nutrient arteries of the heart, and so led to the lesions described above, but the coronaries were free from obvious hardness. Possibly, a patient more willing to rest, from the beginning, might have fared differently. The case is interesting in this further respect, as one of the gravest heart lesions, with an absence of physical signs thereof.

The Pathology of Deaths from Burns.

The *Medical Record*, January 27, 1883, says that Zullner has published more extended reports of the examinations made by him of the corpses of those who perished in the burning of the Ring Theatre, in 1881. All the bodies, even those which exhibited no external marks of injury, were more or less covered with a thick layer of soot. The upper extremities were strongly abducted from the shoulder, the elbows were bent, and the forearms pronated, so that the backs of the hands lay near the face. A fighting attitude was thus simulated in some cases. This was due to shrivelling, and consequent shortening of the muscular fibres, by the action of heat. The large cavities, and more especially that of the abdomen, were often burst, even in bodies not otherwise much injured, and the bowels protruded. In females, the tympanic state of the abdomen frequently simulated a state of pregnancy.

The blood showed every grade of consistency, from the normal, through the viscid state, up to a completely friable dry mass, in which last condition the blood-pigment was found to be in an insoluble state. Occasionally, the blood formed a dull lustrous mass in the uninjured heart and blood vessels. Examined spectroscopically, the blood always showed the bands of carbonic-oxide-hæmoglobin, even in the case of bodies which had remained buried beneath rubbish for a month. In all the bodies which were incinerated, the heart was found in diastole, and rigidly distended with clotted blood. This sometimes gave rise to a suspicion of concentric hypertrophy; but the thin walls of the organ at once revealed the nature of the appearance.

The bones exhibited every stage of burning, from a simple combustion up to a complete calcination. The jaw was mostly firmly closed. The muscles, where the skin was unbroken, had a boiled appearance; but, where they were charred, the odor was that of smoked meat. The drying-up of the flesh, and its permeation by pyrogenous products, obviously retarded the advent of putrefaction. In the eye, the application of lower grades of temperature manifested itself as a tur-

bidity of the cornea, and complete opacity of the lens, giving the appearance of cataract. The larynx, trachea, and nostrils, were often filled with foreign material from the stomach, perhaps due to the vomiting excited by carbonic oxide. The urinary bladder was often full of urine, even when the abdomen had burst. Occasionally, where the bladder was empty of urine, it contained a gelatinous substance with embedded blood-corpuscles. This was found by E. Ludwig to consist of gelatine, probably derived from the connective tissue by the action of heat. Similar gelatinous masses were found in the uterus in some cases; and this organ was found to be very resistant to the action of heat.

Artificial Nephritis.

The *Med. Times and Gazette*, January 27, 1883, says:

Dr. Aufrecht, of Magdeburg, who is already known from his researches on the effects of ligaturing the ureter, has recently published an account of further experimental work in the pathology of the kidney (*Centralblatt f. die med. Wiss.*, November 25, 1882). The ingenious plan was adopted of administering cantharides subcutaneously to animals, and examining the kidneys at intervals after various numbers of injections in different cases. The stages of nephritis could thus be obtained with great ease, and the process followed from one set of renal elements to the others. The general result at first sight appears remarkable. It was found that simple tubular catarrh, tubulo-interstitial inflammation, and ultimately granular disease, were set up by the single irritant cantharides. Dr. Aufrecht is careful to say that it must not be rashly concluded from these observations that Bright's disease is but one and the same process, whatever "form" it takes. The conditions in chronic renal disease in man are obviously totally different from the conditions just referred to. It is, however, an important fact that the tubular disease always precedes the interstitial; and that the latter appears to originate in the connective tissue nuclei, not in the vessels by way of exudation of leucocytes. Acute nephritis induced by cantharides is not indeed attended by any exudation of white corpuscles. It seems obvious that artificial nephritis promises to furnish pathologists with a field for contention almost as large as was furnished by the cornea some eight or ten years ago—Cohnheim's views of the nature of inflammation being still actively combated by other morbid anatomists. In this connection, as well as from its bearing both on the nature of Bright's disease and the possible danger of repeated blistering, we are likely to hear more about artificial nephritis from cantharides. In the same connection, it may be noted that Litten (*Charité Annalen*, VII., page 187, 1882) has observed a case in which inunction with a preparation of balsam of Peru (for scabies) induced acute desquamative nephritis and dropsy on three different occasions.

Bone and Brain Disease in Syphilis.

Before a meeting of the Pathological Society of London, (*Lancet*, December 30, 1882), Mr. Victor Horsley exhibited specimens of Bone and Brain

Disease in Syphilis. The organs shown possess no special interest beyond the fact that successful treatment lessens the opportunities of studying syphilitic lesions. In this case the patient was admitted into University College Hospital under Mr. Hill, from the Lock Hospital, Soho, in a very weak state, and suffering from pyæmic abscesses. What history could be obtained showed his condition to be pyæmic, following on necrosis of the facial and cranial bones. The specimens show, first, the points of necrosis on the frontal and malar bones, together with the spongy bones of the nose, of which the inferior turbinate was found post-mortem to be a mere sequestrum, and kept in the nasal fossa by tenacious mucus. The whole mucous membrane of the pharynx is hyperæmic, and shows a few cicatrices of previous ulceration. The seats of active mischief were excessively foul, the smell of the discharge not being controlled by antiseptics. The frontal bone shows very well the cicatrices of former ulceration and destruction of the outer table. The lungs on both sides showed some cirrhosis of the apices and broncho-pneumonia; the liver, fatty and cirrhotic, presented a depressed scar on its surface penetrating a quarter of an inch into the substance of the organ. Both spleen and kidneys were cirrhotic, while the former was greatly enlarged, being seven inches long by four inches and a half by two inches. The other abdominal organs showed no particular lesion. On removing the brain there was found an excess of cerebro-spinal fluid, while the arachnoid and pia mater at the base were opaque, and in places matted together by exudation. This did not seem to have caused any paralysis of any cranial nerve. There is asymmetry of the cerebellum, the lateral lobe of the left side being deficient on its under surface at the anterior border, the flocculus being scarcely represented. This does not seem to be the result of disease. There were eleven abscesses in the connective tissue of the limbs and trunk.

Physiological Action of the Bromide of Conium.

The *Medical News*, February 10, 1883, says that Prevost (*Arch. de Physiol.*) comes to the following conclusions from an experimental study of this drug:

1. Paralysis from the bromide of conium results from its effects upon the motor nerves, whose irritability is destroyed.
2. If the blood vessels of the posterior extremities of a frog be tied, and then the drug injected, these parts will remain unparalyzed, while the anterior part of the body is affected.
3. In this way, the action of both strychnia and conium can be demonstrated on the same animal.
4. The vagus is affected more quickly than the other nerves, and also regains its normal condition sooner.
5. The secretion of the urine, saliva, and tears, is increased by conium.
6. The conium is excreted in the urine. The urine of a cat which had been poisoned with conium was evaporated to a syrup, and portions of this were injected under the skin of several frogs, in all of which it produced characteristic symptoms of conium poisoning.
7. The secretory nerves preserve their irrita-

bility and augment the secretions, simultaneously with the loss of irritability of the vagus and muscular nerves. However, electrical irritation of the cervical sympathetic and of the chorda tympani arrests the secretion of the saliva. Peripheral irritation of the nerves of the arm induces free perspiration of the palm, when muscular contraction cannot be produced. The same is true of the nerves of the foot.

8. In the warm-blooded animals, if artificial respiration be resorted to, the heart continues to beat.

9. It is doubtful if the nerve centres are at all affected by the poison, for in warm-blooded animals the convulsions were wholly due to asphyxia, and were relieved when artificial respiration was practiced.

10. The irritability of the muscular substance is not affected by the drug.

The Bacillus of Whooping-Cough.

From the *British Medical Journal*, January 27, 1883, we note that Dr. C. Burger, of Bonn, in the first number of the *Berliner Klinische Wochenschrift* for this year, describes at length the special micro-organisms of pertussis, which he states can be found in any specimen of whooping-cough sputum. They appear, under an immersion-lens VII., ocular 0 of Seibert-Krafft, as small elongated elliptical bodies of unequal length, the smallest being double as long as broad. Under a very strong power, transverse subdivision can be detected in the longest specimens. They may form chains or groups, but are generally isolated and scattered singly all over the field. They bear a certain resemblance to *Leptothrix buccalis*, the spores of which are often found in whooping-cough sputum; but the latter are larger and stouter, and near them the filiform mature leptothrix is always present. Occasionally some of the specific bacilli are found to be inside the mucus-cells in the sputum. The bacillus is easily prepared; they can be readily recognized if colored in the usual way by watery solutions of aniline. Fuchsin and methyl-violet were employed by Dr. Burger. As in the case of *Bacillus tuberculosis*, this micro-organism is best studied when mounted in the dry way. Dr. Burger concludes that this bacillus is the actual producer of pertussis, because it is not found in any other kind of sputum, because it is so abundantly produced in whooping-cough that its influence cannot be doubted, because its abundance increases in direct proportion with the severity of the disease, and "because the course and symptoms of the whole disease are best explained by the development of this fungus."

The Physiology of Sugar in the System.

The *New York Med. Jour.*, January 27, 1883, says:

In his new article on "A New Line of Research bearing on the Physiology of Sugar in the Animal System" ("Proc. of the Roy. Soc.," xxxii., 214), Dr. F. W. Pavy concludes that bernardin (glycogen) does not undergo any significant transformation into sugar in contact with blood. Bernardin exists to a distinctly notable extent as a normal

constituent of blood. The evidence derivable from the observations recorded on the addition of bernardin to the blood and its subsequent recovery, and on its extraction from the liver by boiling water on successive days, and by water at 300° Fahr., tends to show that bernardin enters into feeble combination with nitrogenous matter. Bernardin exists in notable amount, not only in muscle, as has been previously known, but also in the spleen, pancreas, kidney, and brain. (He has only examined these structures.) It also exists in notable amount in the white and yolk of eggs. These several products likewise contain a cupric-oxide reducing substance, which is extracted by alcohol, and which, in most instances, possesses the character of glucose, but specially, in the case of muscle, the character of maltose. Through the existence of glycogen throughout the system, as has been represented, we have a carbo-hydrate occupying a parallel position to albumen—viz., existing in a colloidal state, and thus adapted to retention in the body, instead of passing off as a diffusible substance, as glucose tends to do.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—"Modified Listerism," is what Dr. Edward W. Jenks, of Chicago, recommends in ovariectomy. (Reprint.) What this amounts to is really not much more than "careful attention to perfect cleanliness." No doubt this is sound doctrine; but it is giving Lister more than his due to attribute to him the discovery of the benefits of cleanliness!

—A valuable reprint is that of a series of articles by Dr. J. Marion Sims, "On the Treatment of Gun-shot Wounds of the Abdomen in relation to Modern Peritoneal Surgery." London, pp. 32. His conclusions are the result of an experience hardly equalled by any of his contemporaries.

—The prevention and treatment of blennorrhoea of the new-born infant, is the subject of a monograph, recently reprinted, from the pen of Dr. M. Landesberg, of Philadelphia. In inflammatory cases he has found eserine of much service.

—The latest issues of the Health Primers published by D. Appleton & Co., New York, are "The House and its Surroundings," and "Premature Death, its Promotion or Prevention." They are well written and well printed, though better adapted to English than American life and surroundings. For this reason we should prefer sanitary treatises by authors of our own country.

THE
Medical and Surgical Reporter,
 A WEEKLY JOURNAL,
 ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
 JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
 115 South Seventh Street,
 PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
 OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

THE SOUNDS OF THE HEART.

The time has long gone by, says Dr. W. H. Broadbent, in the January number of *The Practitioner*, when the recognition of a murmur at the base or apex, systolic or diastolic in time, or even of obstruction or regurgitation at one or other of the orifices or valves, could be accepted as an adequate diagnosis of heart disease. If a valvular lesion exists, the degree of obstruction or the amount of regurgitation must be estimated, the condition of the walls and cavities of the heart must be ascertained, and the effects of the interference with the current of blood must be traced. But in a large majority of affections of the heart, and these some of the most deadly, there are no murmurs from first to last, and we have to seek the elements of a diagnosis in other evidences of structural change or functional failure, in the seat and character of the apex beat, in the situation, extent, force, and character of the impulse elsewhere than at the apex, in the dimensions of the heart and the relative size of its different chambers as revealed by percussion, and in modifications of the sounds.

When, in enteric fever, the first sound becomes short and feeble, or ceases to be audible, there is considerable danger. The left ventricular sound is somewhat prolonged and more dull when the ventricle is hypertrophied. It is in dilatation of the left ventricle that the short first sound is most common. When it is at the same time loud and low in pitch, the dilatation may be considered to be accompanied by some degree of compensatory hypertrophy; when the ventricular wall is thin, it will be sharper, and when the heart's action is weak, this sound will also be weak. In fatty degeneration, the first sound is peculiarly short and sharp but weak, and there is no true impulse or push, but only a tap against the chest wall. In mitral stenosis it becomes extremely short and sharp, and when the presystolic murmur is lost, this may constitute the main element in diagnosis. A weak aortic second sound (heard in the second right intercostal space, close to the edge of the sternum, and from this spot

upwards to the right sterno-clavicular articulation, and also over the carotids), not the result of valvular disease, is evidence of a weak ventricular contraction from some cause or other, while a lowered pitch and a ringing tone is indicative of dilatation or aneurism of the aorta. Reduplication of the second sound is a frequent effect of mitral stenosis and pericarditis.

When compensatory hypertrophy is failing and dilatation is the predominant feature, the occurrence of the second sound is most strikingly delayed, and the increased duration of the systole is all the more conspicuous from the fact that in this condition of the heart the first sound is usually short and sharp. The combination of a short first sound, with a prolongation of the interval between this and the second sound, causing a tic-tac rhythm, is very frequently met with in renal disease. This same tic-tac character is usually marked in fatty degeneration of the heart, though it is not diagnostic, as the rhythm has been preserved in cases where the clinical history and mode of death was suggestive of fatty degeneration. The feeble, distant ticking is most striking in large effusions into the pericardium, but it may occur in advanced degeneration and dilatation.

In extreme cardiac asthenia, from fatty degeneration, acute dilatation or the late stage of chronic dilatation, the interval between the first and second sound may be abnormally short. When the second sound follows the first immediately, the danger of future syncope is great.

THE MISSION OF MEDICAL JOURNALISM.

When we stop to reflect for a few minutes on the mission of medical journalism, we are struck with its sublimity and importance.

If it is grand and noble for a man to go about among his suffering fellows, bringing relief and scattering morsels of comfort to the sick and afflicted, how much grander and nobler is that factor that gives to him the power to thus avert or correct the multitudinous evils to which fallen human nature is heir-apparent.

It is primarily to his medical journal that the physician is indebted for his medical knowledge.

All the progress, all the advance in the various departments of medical science, all new operations, every novel instrument, all that is new in every branch of our own and collateral sciences, first sees the light of day in the columns of our medical journals, from which, after a time, that which has possessed sufficient merit to stand the searching test of critical experience, is transferred to the pages of text-books. It is, comparatively, rarely that any *absolutely new* matter is found in medical books; this is not an absolute rule, but it is one to which the exceptions are very few and very far between; the great proportion of the matter found in text-books has been transferred from the journalistic columns. Some literateur, who, combined with a love for reading, an assortive mind, and a quick perception, possesses powers of discrimination, arrangement, and a pleasant style of writing, will cull from these journals, here and there, whatever may have been proved really valuable, and will arrange them in appropriate order, adding a little of his own personal experience, if he has had any, and his finished production constitutes the particular text-book.

If, then, this material is to be found, fresh and at first hand, in the medical journals, it is evident that he who would keep pace with professional progress, must read these journals.

Again, in order that the columns of these journals should be valuable, it is evidently necessary that physicians should write for them. By following out the advice we gave in a recent editorial on "The Collective Investigation of Disease," and keeping such records as were therein recommended, every man in active practice could find something to communicate that would prove both valuable and instructive.

The gift to felicitously express one's self in writing is rare, but this should not deter a man from writing. When you have something valuable to communicate, though you may be unable to do so in the easy-flowing language of De Quincey, yet the solid, substantial facts are there, and no matter howsoever homely may be your expression, yet such a communication will benefit your

profession and redound materially to your reputation and your benefit.

We would advise all physicians to subscribe to and regularly read as many medical journals as their means will allow, and urge upon them to cultivate the habit of writing short, practical communications for publication.

INSTRUCTION IN MENTAL DISEASES.

A most praiseworthy effort has been set on foot looking to the instruction, both didactic and clinical, of medical students in mental diseases, and it is one that deserves most hearty support and co-operation.

Realizing that insanity, in its incipency, must always pass under the observation of the general practitioner, before the patient be definitely committed to the expert as insane, an acquaintance with its phases is a necessity to the practicing physician.

A committee, consisting of Drs. E. C. Seguin and M. Putnam Jacobi, of New York, and Margaret A. Cleaves, Harrisburg, have issued a circular to our various medical colleges in which they recommend such instruction by means of—

1. *A chair or lectureship on psychiatry.*
2. *A clinic of psychiatry, held in an asylum for the insane.*

It is stated that nearly a dozen schools in this country already advertise lectures on insanity as a part of their course.

While we thoroughly appreciate how great are already the labors imposed on students in our best institutions, yet this innovation seems so manifestly demanded, in the interests of humanity, that it really is strongly entitled to consideration.

VACCINATION IN MALIGNANT CHARBON.

When the results obtained by M. Pasteur through the inoculation of the attenuated virus of malignant charbon were published, it was considered a scientific experiment, and but few thought that any practical benefit would accrue therefrom. The report recently presented to the veterinary society of the department of Eure-et-Loire, show that these vaccinations, practiced on a large scale,

have given unexpected results. The number of sheep vaccinated in this department was 79,312; the annual loss on these flocks amounted to 7,237 animals, or about 9 per cent.; since vaccination but 518 animals have perished, or about $\frac{6.5}{100}$ of 1 per cent.

It is true that the general mortality from charbon among the sheep in the department was lower than usual (about 3 per cent.), so that the loss among these 79,312 sheep would have been 2,382 instead of 518 after vaccination.

In flocks partly protected, the mortality among 2,308 vaccinated animals was 8, or $\frac{4}{10}$ of one per cent.; and among 1,659 non-vaccinated, 60, or $\frac{3.6}{10}$ per cent. In these flocks the vaccinated and unvaccinated were under exactly similar conditions as regarded food, stable, temperature, etc.

The veterinary surgeons vaccinated 4,652 cattle, among which the annual loss from charbon was 322 animals; since vaccination but 11 cows were lost, showing a reduction in the annual mortality from $7\frac{3}{10}$ per cent. to $\frac{2.4}{100}$ of one per cent.

As the mortality from charbon among horses was light, and vaccination induced glandular enlargements, the operation was not undertaken on a grand scale.

TIME WASTED IN DRUG STORES.

We have been requested by many parties, time and again, to have something to say about the annoying way in which their valuable time is consumed by delays in drug-stores.

We do this the more willingly, because we thoroughly realize that their complaint is a just one.

Dispensing druggists, as a rule, seem to forget that ordinary business principles ought to guide them; and in some cases, where a dear relative is very ill, the delays, which are so evident to the one waiting for medicine, will surely lose to this particular druggist a goodly share of trade. One of our complainants went recently to a first-class pharmacy for a certain medicine, at two o'clock in the afternoon; they did not have it, but the *obliging* clerk said he would get it in fifteen minutes. After sending for it *twice* in the interval, it

was received at six o'clock. In all kindness, we would urge upon druggists the cultivation of that trait which is so eagerly sought after by those in all other lines of trade, viz., *promptness in executing orders.*

THE STUDY OF VETERINARY SCIENCE.

It was a gratifying evidence of the practical progress of scientific pursuits with the needs of the world that was witnessed at Chickering Hall, New York, on February 27th, when the American Veterinary College held its eighth annual commencement.

It is pleasing to all properly-disposed persons to see evidences of interest in the welfare of the brute creation, which was made strikingly evident by the number of distinguished gentlemen at this commencement. The degree of Doctor of Veterinary Surgery was conferred upon twenty-two graduates.

We are soon to have a Veterinary Department in the University of Pennsylvania, and it is but a short step to the time when veterinary medicine and surgery will possess its own respectable and legitimate position in society.

NOTES AND COMMENTS.

Movable Kidneys.

Dr. E. C. A. Bains, referring to the fact that Mr. Lawson Tait had said that he had never seen a floating kidney either in life or in a museum, describes the following case in the *British Medical Journal*, January 13, 1883. S. B. aged 67, had suffered from albuminuria for several years. Six months ago she consulted me about a tumor, which she said both she and her daughter could move from "front to back." On examination, I found a floating kidney lying close to the right anterior superior spine of the ilium, and I could readily replace it to its proper position. It had never caused her the slightest pain or inconvenience. On November 17th she died, after a few days' illness, from pneumonia. On November 19th I made a *post-mortem* examination in the presence of a pupil of my partner and our assistant. I found that the kidney could be moved several inches without detaching it. On section it presented the following appearances: The kidney-structure had entirely disappeared, in its place

was a sacculated cavity. The pelvis of the kidney was occupied by a calculus, weighing four drachms, shaped like a map of Italy. The left kidney was enlarged and congested.

Eucalyptus Oil in Obstetric Practice.

Dr. Sloan awards very high praise (*Progrès Méd.*) to eucalyptus oil as a preventative of puerperal septicæmia. He recommends it more particularly in cases where there has been effraction of the tissues.

The following mixture may be used to assure uterine contraction after labor:

R.	Sol. morphis chlorhydrat (B. Ph.)	gtt.-xc.
	Tr. nucis vomic.,	f. 3 ss.
	Ext. ergot fl.,	f. 3 ij.
	Tr. aurantii,	f. 3 iij.
	Aque ad.,	f. 3 ij.

M.—One drachm may be given every 4 or 6 hours. Twice daily injections containing carbolic acid or permanganate of potash.

According to Dr. Sloan, eucalyptus oil offers the following advantages: It is not poisonous, it is not irritating, and does not coagulate the lochial discharges. Its odor is generally agreeable, and it appears to aid uterine contraction.

The author employs it in form of pessaries composed as follows:

R.	Ol. eucalypt.,	5 iv.
	Cera alb.,	f. 3 ij.
	Ol. theobrom.,	5 iv.

M.—For 12 pessaries. Another combination which sometimes proves too irritating, contains 24 grams of the eucalyptus oil.

Dr. Sloan reports cases where these suppositories have been of great service, and one in particular where subcutaneous injections of the oil diluted with olive oil seemed to save a patient almost ready to succumb.

Treatment of Increased Arterial Tension.

In the *Brit. Med. Jour.*, February 3, 1883, Solomon Charles Smith, M. D., Surgeon to the Halifax Infirmary, after discussing this subject, and dwelling at length on the physiology of the circulation, concludes that the presence of increased arterial tension or blood-pressure involves the existence of obstruction at one end, and increased heart-force at the other: that it is important to distinguish between these two conditions; that the form of trace usually considered indicative of high tension really only shows obstruction, which, while necessarily occurring with it, may also occur by itself; that the measure of the tension is the pressure required to stop pulsation in the

artery or the circulation in the limb; and that while we should always try to reduce abnormal obstruction, we should but seldom interfere with the tension as such, unless it threaten danger to the heart or vessels.

Fistula in Ano.

An exhaustive discussion on the treatment of fistula in ano took place before the Société de Chirurgie (*Union Med.*, October 10-17, 1882). M. Lucas-Championnière advocated the ligature and reported five successful cases. M. Verneuil protested against its use, preferring Paquelin's cautery. M. Després favors the écraseur and the bistoury; with the latter he has operated in 220 out of 230 or 240 cases, never had hemorrhage, and never lost a patient from purulent infection; but he always prepares his patients by a week or two of repose, lotions, and baths. The écraseur he has used ten or twelve times, and never had a relapse. It was contended that no general rules of treatment could be laid down, but that each case must be studied as to the indications for the line of operative procedure.

Obscure Cancer of the Stomach.

Mr. Raymond, in the *Progrès Médical*, No. 52, 1882, and No. 1, 1883, relates a case in which the only symptoms were cachexia, generalized œdema, and serous diarrhoea. There were no physical signs to explain these symptoms. There was no dyspepsia. At the post-mortem all the viscera were found healthy, except the stomach, in which were found a number of sub-mucous greyish tumors, varying in size from a small apple downwards. They were non-pedunculated and there was no ulceration. On microscopical examination these tumors were composed of alveolar stroma, enclosing large cells of very varied forms, some flat, others rounded. It is somewhat strange, perhaps, that the secretion of gastric juice was not more interfered with than it seems to have been. Such a case as this is quite beyond the reach of legitimate diagnosis, with the means at present at our disposal.

Danger from Cinnamon-Colored Clothing.

A death is reported to have recently occurred in Warsaw in consequence of the victim wearing cinnamon-colored clothing. The dye faded under the influence of perspiration, and was partially absorbed through the skin. Poisonous matter contained in the dye caused death. The first symptoms were vertigo, bleeding from the mouth, and loss of sight. The case baffled the skill of

the physicians. Every remedy was tried in vain. Before he died, the patient gave the name of the dealer from whom he bought the clothing, and the police are investigating the subject. A solution of the dye given to a dog caused death in an hour.

To Disguise the Taste of Quinine.

Mr. J. K. Lilly proposes for this purpose a syrup of Yerba Santa, the formula for which he gives in the *Chicago Med. Rev.*: "Fluid extract yerba santa, four parts; water, eight parts; powdered pumice, one part; granulated sugar, fourteen parts. Mix the fluid extract with the water, evaporate to seven parts, shake with pumice, allow to stand, decant, add sufficient water to preserve measure, then with heat dissolve the sugar. The addition of fluid extract of licorice in the proportion of half a drachm to the ounce of syrup, or of aromatics, adds somewhat to the elegance of the preparation."

Venus's Fly-Trap.

In the course of his lectures on "Human Automatism" (*New York, Med. Jour.*, January 27, 1883), Dr. W. B. Carpenter made reference to the Venus's fly-trap as described by Mr. Darwin. It has a leaf consisting of two broad expanded lobes, with prickles upon the surface of each; and it is sufficient to touch either of these prickles for the lobes to fold together so that the sharp spines which project from the edge of each, cross those of the other, inclosing any unfortunate insect that has alighted upon the leaf; and upon them the plant lives and grows.

Tonsillotomy in Children.

Referring to the operation for the removal of enlarged tonsils, affecting the physical growth of children, Dr. W. H. Daly says in *The Medical Record*, February 10, 1883, that it has always in his experience been most positive and flattering in the highest degree; so much so that he never hesitates to assure the friends that they may look for improvement in the physical status of the child, and he is never disappointed, especially if proper treatment is carried out with reference to the cure of concomitant catarrhal disease of the naso-pharynx.

The Injudicious Use of Quinine.

Dr. D. B. St. John Roosa wisely calls attention to this pregnant question in the *Medical Record*, February 10, 1883. Admitting and realizing the great value of this drug in all affections of a true

intermittent character, he condemns in unmeasured terms its household use, and warns the public against the prevalent habit of using it to "break up" a cold in the head, which it often intensifies by the cerebral hyperæmia which it induces. It may cause serious disease of the eye or ear, and he considers it absolutely valueless in pyæmia.

Pilocarpin in Puerperal Eclampsia.

Dr. Cantilena reports a case of a woman unconscious with puerperal eclampsia. There was slight œdema and albuminuria. Many measures had been unavailingly tried, and there were little hopes of recovery. A hypodermic injection of $\frac{1}{2}$ of a grain of muriate of pilocarpin was given and repeated in five hours. There was abundant perspiration and salivation, with marked improvement. The injection was repeated twice on the ensuing day, and a perfect recovery resulted.

Dry Cupping and Rest in Locomotor Ataxia.

Dr. Henry M. Lyman considers that even if these means possess no curative power, yet if they did no more than merely relieve pain, which they do, they would be invaluable. He says (*Chicago Med. Jour.*, January, 1883): "Its effect upon the general health and nutrition gives it the right, in this case at least, to rank with hydrotherapy, massage, and the Swedish movement cure, as a method of treatment which deserves trial as a means of retarding the progress and relieving the anguish of one of the most intractable of diseases."

Compound Fracture of Femur.

In the *British Medical Journal*, January 20, 1883, Dr. Arthur E. Barker reports a case of compound fracture of the femur, complicated with erysipelas and pyæmia, in which the thigh was amputated, and subsequently exarticulated at the hip, with complete recovery. The patient was a healthy man aged twenty-nine, and the good result was, in a great measure, attributed to the complete rest, local and general, which was rendered possible by the use of the unfrequent dry antiseptic dressing, in the subsequent treatment.

Removal of a Large Bronchocele.

The *Med. Record*, February 10, 1883, records that Dr. Cheever, of Boston, removed, quite recently, a large bronchocele at the Boston City Hospital. The tumor weighed ten ounces. The right and left lobes were dissected in turn from their beds by the usual incisions, and the thyroid and other arteries tied before they were severed.

The amount of blood lost was inconsiderable, scarcely equaling eight ounces. The patient subsequently died of shock at the end of twenty-four hours.

The Antiseptic, Glacialine.

New Remedies, for January, 1883, says that according to Dr. Besana, this substance, which has met with so much favor in England and elsewhere as an antiseptic, especially for the preservation of milk, meat, and other articles of food, has the following composition: Boracic acid, 18 parts; borax, 9 parts; sugar, 9 parts; glycerin, 6 parts. A Roman composition of a similar kind was found to be nothing but pure boracic acid.

Plantago Lanceolata as a Styptic.

The plantain juice does not contain tannin, but Professor Quinlan (*Phar Jour.*, No. 637, 1882,) has derived excellent results from its use (chewed form or dried leaves) as a styptic application in external hemorrhage and internal bleeding from lungs, kidneys, and bowels. In menorrhagia he has had fair results from large and repeated doses of the juice, either fresh or mixed with alcohol or glycerine.

Alcohol in Scarlatina.

Dr. Giles Mitchell reported to the Cincinnati Academy of Medicine forty-three consecutive cases of scarlatina treated with large doses of alcohol, without a single death. A half ounce of whiskey every hour was given to a child two years old for a number of days, without the slightest sign of intoxication. When the kidneys became implicated, the alcohol was still used. It always produced a fall of temperature. The report is found in the *Medical Times*.

Cure of Abscesses of the Neck Without Cicatrises.

Dr. F. J. B. Quinlan recommends the passage through the abscess of a fine silver wire, and the ends tied outside, when it will act as a drain. This must be done before the pus reaches the surface, when it is, say half an inch from the external surface. No poulticing or stuping must be used, and when the abscess is evacuated a compress applied. This procedure has never failed in his hands.

A Successful Nephrectomy.

Mr. Morrant incised the pelvis of the kidney in a boy aged sixteen, giving vent to about thirty ounces of purulent fluid, which produced very beneficial results. This improvement, however,

was not maintained, and the *British Medical Journal*, of January 20, 1883, tells us that on the 28th of last December the whole of the kidney was removed piecemeal. Up to January 18th he was progressing favorably.

Simonnot's Anti-Blennorrhagic Boluses.

The *Jour. de Med. de Paris* gives this formula :

R. Copaiba balsam,	℥vj.
Powdered cubebs,	℥ijj ℥viss.
Wax,	℥ijj.
Powdered rhatany,	℥ij℥.
Carbonate of magnesium,	℥iss.

To be made into boluses of 15 grains each, which are to be rolled in subcarbonate of iron, and coated with an ethereal solution of tolu balsam and mastic.

Nerve Stretching.

Dr. John A. Wyeth finishes a short report on this subject in the *American Journal Neurol. and Psych.*, November, 1882, with the following conclusions :

1. A simple operation, comparatively free from danger, will afford temporary relief from pain so atrocious that even temporary surcease justifies the risk and its repetition.

2. That the muscular ataxia of *tabes dorsalis* is very slightly, if at all, relieved by this operation; certainly not enough to justify it.

Tolerance of Chlorodyne.

Dr. Henry Barnes (in the *British Medical Journal*, November 25) reports the case of a young woman who had been a hospital nurse, and who had contracted a habit of dosing herself with chlorodyne. Her usual dose was a bottle, which contains $2\frac{1}{4}$ oz., and a $\frac{3}{4}$ v. bottle only lasted her little more than 24 hours. She was under treatment, and was slowly recovering.

Nasal Disease a Cause of Asthma.

Voltolini first directed attention to the relation of cause and effect between polypus of the nose and asthma, but now Dr. G. Hunter Mackenzie calls attention in the *Edinburgh Med. Jour.*, February, 1883, to a case in which simple chronic inflammation of the nasal mucous membrane, without a polypus, was clearly the cause of aggravated and persistent attacks of asthma.

Mercurial Glycerite.

According to Dr. Vigier, drugs incorporated with glycerine are not at all absorbed, but mercury with lard is absorbed, and he therefore

recommends the following (*Gaz. Hebdom. de Med.*) as an anti-parasitic mixture, that will not be absorbed, in scabies, pediculi, etc.

R. Hydrarg. bichlorid.,	℥iss.
Glycerine,	℥ijj.
M.	

Paraldehyde as an Hypnotic.

Dr. Vincenzo Cervello, of Palermo, says that paraldehyde in doses of 30 to 45 grains induces a quiet, reparative sleep, not followed by headache, loss of appetite, or mental confusion, as after chloral. It is very useful in the periodical mania of progressive paralysis, in acute and chronic mania, delirium tremens, etc.

Paralysis from Slight Handling of a Nerve.

Dr. Alfred C. Post, of New York, removed a neuroma from the median nerve, which he succeeded in enucleating without injury to the nerve. The next day (*N. Y. Med. Jour.*, January 6, 1883), there was paralysis of both motion and sensation of the forearm and hand, not absolutely complete, but nearly so. The patient is now gradually recovering.

An Improved Catheter.

The lower end of the ordinary catheter offers a comfortable resting-place for bacteria, etc., which Dr. Hupeden thinks are very active in prolonging chronic vesical catarrh. He therefore recommends in the *Berliner Klin. Woch.*, January 15, 1883, that the instrument be made solid up to the openings in the side, which will greatly facilitate cleaning.

Indicative of Hepatic Abscess.

Dr. J. Kingston Fowler (*Lancet*, January 20, 1883), is strongly impressed with the fact that when obscure disease, e. g., pleurisy with doubtful pneumonia, at the base of the right lung, is associated with profuse sweating, the formation of an hepatic abscess should be suspected.

Exhausted Linseed Meal for Poultices.

M. Lailler (*Rep. de Phar.*), thinks that linseed meal which has been deprived of its oil is superior to that which has been freshly ground and used in its natural state; it retains its heat longer, while when the oil is present, it becomes rapidly rancid and seriously irritates the skin.

The Significance of Peptonuria.

Dr. Jaksch (*Wiener Med. Woch.*, No. 42, 1882), thinks the excretion of peptone in the course of pneumonia, acute articular rheumatism, menin-

gitis, etc., indicates that the inflammatory process is subsiding.

Death from Dichloride of Ethidene.

The *Lancet*, January 27, 1883, records the death of a man who was anesthetized with the above agent. Nitrite of amyl, and artificial respiration for an hour, were useless. The heart was flabby, thin and extensively degenerated; the valves were healthy.

The Immediate Removal of the Secundines after Abortion.

Dr. Paul F. Mundé contributes an article on this subject to the *Amer. Jour. of Obstet.*, February, 1883. From a review of 57 cases, he concludes that the safety and utility of the forcible removal of the secundines is abundantly proved.

Rupture of the Heart.

Survival for forty hours, after a rupture half an inch long in the posterior wall of the left ventricle, is so unusual that the case described by Dr. S. Coupland in the *Lancet*, December 2, 1882, is worthy of record.

Sodium Bicarbonate in Acute Tonsillitis.

Dr. J. O. Skinner, U. S. A., corroborates, in the *Med. News*, Dr. Stuver's experience with this drug. He places great reliance on it, combined with tincture of myrrh and camphorated tincture of opium in water, used as a gargle.

To Make Boracic Acid Ointment.

This is not easy, but can be accomplished by rubbing the acid with enough glycerine to make a soft paste, heating slightly over the flame of a spirit lamp or gas jet, and then adding the unguent and stirring until thoroughly mixed.

Adonis Vernalis.

This is a popular remedy in Russia for heart disease and dropsy. It stimulates the motor and inhibitory ganglia of the heart, and is not cumulative in its action. A glucoside "adonidini" has been isolated.

The Endermatic Use of Quinine.

Dr. Galanti, of Rome (*Gaz. Med. di Roma*, No. 19, 1882), uses an ointment of sulphate of quinine, applied to a blistered surface, in the malarial pneumonia of children.

CORRESPONDENCE.

Medical Ethics.

EDS. MED. AND SURG. REPORTER:—

The well-informed practitioner of medicine is aware that for many long centuries the healing art and the priestly office were united in one, and that there was a strong tendency in the priest-physician to introduce into his practice secrecy, pretence, incantations, and exorcisms. These ages of ignorance and superstition have passed away, as we generally suppose, but their shadow still lingers upon the profession. We have not yet reached the clear light of day. The incantations and exorcisms may not be tolerated except in families distant from school-houses, but the secrecy and pretence are practiced everywhere.

The best statistical information that can be obtained shows that ninety-five per cent. of practitioners in foreign countries, and about eighty-five per cent. of American physicians, agree in this: that the practitioner, in his relations with the people and the profession, should not make use of a name by which he may distinguish himself from his fellow practitioners except that name which was given to him by his parents. To illustrate: Why should any practitioner place upon his sign or card such qualifying words as Indian Doctor, Botanic Doctor, or Eclectic Physician, or Homeopathic Physician, or Hydropathic Physician, or Hygieo-Therapeutic Physician, or Vilopathic Physician, or Omnipathic Physician? This array of high-sounding terms ought indeed to alarm those who make use of them, especially since every few years a "new school" of practice is announced. An evil of this kind, growing in our country by the aid of mercenary legislators and executive officers, has no cure except in the use of the daily newspapers on the side of honorable scientific practice.

But what should be our relations with these sects in medicine? This is the question which specially concerns us at the present time. Shall we affiliate with them, and accept their interpretation of the golden rule? Where shall we draw the line between truth and error, scientific practice and quackery? We have made an honest effort to do this. Have they ever indicated where this line should be drawn? No, they cannot agree except in the use of some name, which the people cannot interpret.

But it has been assumed that a political legislature can establish honorable relations between medical practitioners, and the announcement has been made; but how can this be done except by placing scientific truth on a level with whimsical theories, or honor on a level with pretence? Can a legislature define the duties which we owe to the sick, to one another, and to the community at large? If so, then every state can have its own code of morals, or no code at all. In either of these cases, divisions and strifes would multiply instead of diminish; there could be no union. Remove the keystone, and the arch falls.

The American Medical Association has adopted what is known as a Code of Ethics—an admirable instrument, but by no means perfect. The few lines which relate to this subject are obscure, and the words, "exclusive dogma," when transferred to

a political or religious newspaper, are offensive to the people, and to many in the profession. We do not object to any one holding a theory or doctrine, however absurd it may appear to some; but we do object to the practitioner making use of pretentious or deceptive language in a newspaper, on his sign or card, or in his intercourse with the people. The exclusion of any one from consultations should not be based upon any theory or doctrine the practitioner may hold, nor upon his style of practice, but upon unprofessional conduct, which would include gross immoralities, as well as the use of language which produces division and strife. The attorney-at-law is stricken from the roll for unprofessional conduct, and the people endorse the action of the court.

R. LOWRY SIBBET, M. D.

Carlisle, Pa.

An Ounce of Chloroform Taken with Suicidal Intent—Recovery.

EDS. MED. AND SURG. REPORTER:—

When I arrived at the bedside of the patient, fully forty-five minutes had elapsed since she had swallowed an ounce of chloroform. The patient is thirty-six years old, and has suffered for fifteen years with some kind of uterine disease, and, becoming tired of life, attempted to end her sufferings as above indicated. I found her in a close room, her head elevated on pillows, and her lungs just perceptibly in motion. I lowered her head, then opened the windows, let a draught of air blow over her, and injected a drachm of brandy hypodermically. She soon ceased to breathe. I then commenced artificial respiration, and continued it without a moment's intermission for fully two hours. During the two hours I injected four ounces of brandy at regular intervals, using a syringe-full at each injection. I also injected one-tenth of a grain of digitaline, which lessened the rapid beating of the heart, then going at literally an uncountable speed. Nitrite of amyl, a few drops on a handkerchief and held to her nose at various intervals, acted very promptly, flushing the face and strengthening the respirations. After fifteen hours of unremitted watchfulness, I had the satisfaction of saying to her two daughters that their mother was safe. The soreness arising from the punctures of the syringe caused some trouble for a few days, but the patient is now doing well, and seems more cheerful in mind than formerly.

C. H. MERRICK, M. D.

Seattle, Washington Territory.

NEWS AND MISCELLANY.

Current Diseases.

A report from Waterbury, Conn., states that an epidemic of winter cholera prevails there, caused, it is thought, by the snow water in the city reservoirs. About 250 persons have been attacked.

In Lawrence, Kansas, smallpox has broken out among the colored population.

Twenty persons in Malaga, Spain, have, it is said, been attacked with trichinosis from eating American-cured hams.

Commencement of the Medical Department of the Arkansas Industrial University.

The annual commencement of this institution took place at Little Rock, February 28, 1883. The degrees were delivered by Governor Berry. Dr. P. O. Hooper, President of the College, presided.

Convicting a Midwife.

The midwife (recently referred to) who had infected a number of women with syphilis through attending labors while suffering from a chancre on one of her fingers, was last week found guilty, and sentenced to twelve months' imprisonment with hard labor.

The New York Code.

We learn that a society is being organized in the State of New York, whose object is to maintain the Code of Ethics of the American Medical Association. A large number of the leading members of the profession have expressed their desire to join the society and become active co-workers.

German Eye and Ear Infirmary.

For the year 1882, there have been gratuitously treated at the German Eye and Ear Dispensary, 314 Noble street (Dr. M. Landesberg, surgeon in charge), 1,516 patients, of which number 1,028 were for eye diseases, and 488 for ear diseases. The number of important operations performed in the Institute was 135, of minor 175.

Extending the Code.

Dr. F. H. Darby, of Morrow, Ohio, has printed a sheet of selections from the Code, especially with reference to the duties of patients to their physician, interspersing it with light and readable matter. He will sell these sheets at about cost, and they can be used as wrappers, etc. A specimen can be obtained from him by mail.

American Public Health Association.

The next meeting of this Association will be held in Detroit during the second week in November, 1883. The executive committee announces the principal topics for discussion to be, (1) The best method of collecting and publishing vital statistics. (2) The etiology of malaria. (3) Food preservation and adulteration, and (4) The physics of house drainage.

Journals of Paris.

According to the *Annuaire des Jour. de Paris*, published by Brunox, 1,291 journals, weekly, monthly, etc., appear at Paris; of these, 59 are religious journals, 118 relate to jurisprudence, 240 to political economy, commerce, and finance, 22 to geography and history; light literature claims 128; instruction, 38; literature, philology, and bibliography, 62; the fine arts, 11; photography, 3; architecture, 9; music and the theatre, 44; the fashions (modes), 73; the diverse industries, 138; medicine and pharmacy, 92; the sciences, 57; military and naval subjects, 24; ag-

riculture, 28. The number of daily political journals is 67. The number of journals relating to finances (stocks, etc.), the diverse industries and educational subjects, has much augmented, while the others remain stationary.

Dark Ways of Some New York Doctors.

A bill was recently introduced into the New York Senate by Mr. Pitts to prohibit medical societies from adopting rules forbidding practitioners from conferring with others than those of their own school of medicine.

This looks like a desperate endeavor on the part of those New York specialists who are itching to consult with all sorts of irregulars in order to increase their income.

A Naval Medical Society,

The medical staff of the Navy has organized a Society called "The Naval Medical Society," in order to establish more intimate social and friendly relations among its members, to furnish occasions for the interchange of professional experiences, and to assist each other in scientific inquiry and research. Every officer of the medical corps has the right of membership upon notifying the Secretary that such is his desire.

The Society is to have regular meetings on the first Thursday of every month, in the city of Washington, and at such other times as the business committee may consider advisable, or when five other members may so request.

Epidemic Diseases in Paris During the Year 1881.

This report, confided by the Conseil d'Hygiene to M. Lagneau, necessitated the examination of thousands of documents, and required considerable time in preparation. It concerns the whole Department of the Seine, which contains 2,799,329 inhabitants. In the department, the deaths from this class of diseases during 1881 were as follows:

Diphtheria	2,690
Typhoid Fever	2,315
Smallpox	1,182
Measles	1,009
Cholera and Cholericform Diarrhœa	860
Whooping-cough	549
Scarlatina	463

The statistics fell short of reality as regarded the number of deaths from puerperal affections, for such diseases were carefully reported only in hospital services. An interesting fact was noted, that in the arrondissements of Sceaux and St. Denis, without the walls of the city, the number of deaths from these diseases was the same in proportion as in the city itself. M. Lagneau calls attention to the fact, that the number of deaths from diphtheria, typhoid fever, and measles, increases every year in Paris. The same fact was brought forward by M. Bronardel, in the Soc. Méd. des Hopitaux, and he showed that the hygienic condition of the city left much to be desired.

The Conseil d'Hygiene has not sufficient powers, and its recommendations are disregarded. The creation of a Board of Health similar to those in function in England, Germany, and the United States, is imperatively required.

The Anti-Vaccination Agitation in Germany.

The *Medical Times and Gazette*, January 20, 1883, says:

The Anti-Vaccination League, which seems to be taking a little rest in France, continues its agitation in Germany. It is not only syphilis which vaccination is accused of transmitting, but (according to a letter addressed to the Paris Académie de Médecine by the French Ambassador at Berlin) likewise other redoubtable diseases, especially scrofulous affections. This new ground of accusation is derived from Dr. Koch's experiments, and the authority which this *savant* enjoys explains the emotion which has laid hold of public opinion. Thus a true shower of petitions seems to have fallen on the Reichstag, which has appointed a committee to examine them. The conclusions of this committee point to the organization of a complete investigation of the results furnished by the law of compulsory vaccination in Germany, and of a proposed law relating to epidemic diseases in general. The materials accumulated by this committee will be laid before the Reichstag by the government.

Items.

—Typhoid fever has appeared in the inundated districts of the Ohio Valley.

—The Second German Congress for Internal Medicine meets at Wiesbaden, April 17 to 20, 1883.

—The disinfectant sold under the name Listerine is highly esteemed by those surgeons who have tried it.

—The Louisaina State Medical Society will hold its next meeting at Shreveport, La., on Wednesday, April 4, 1883.

—The annual commencement exercises of the Buffalo Medical College were held February 27. Diplomas were conferred on fifty-six graduates.

—"Neuralgia" is the name borne by a charming girl of Iowa. Her mother found it on a medicine bottle, and was captivated by its sweetness.

—The citizens of Cincinnati are urging the passage of a bill appointing a street and sanitary commission for two years, with \$1,000,000 to spend.

—There are nine general and seven special medical journals published in New York city. There are four weeklies, seven quarterlies, four monthlies, and one bi-monthly.

—In the ruins of Pompeii has been lately discovered a quadrivalve speculum, exquisitely proportioned, with a movement unsurpassed by the most perfected of modern instruments.

—The total number of deaths in St. Louis for the year 1882 was 7,817. This makes the annual death-rate 19.5 per 1,000, estimating the population at 400,000. The number of births during the year was 8,441.

—A case is reported of fracture of the hyoid bone from gaping in a man, æt. 27. For three weeks there was exquisite pain on touch, and great pain and distress in deglutition. The patient recovered, although he suffered much from inanition.

—Professor L. McLane Tiffany has lately, at the University Hospital, Baltimore, successfully ligated the common femoral artery just below Poupart's ligament for an aneurism of that vessel due to a stab.

—In a recent report of the registrar at Borrisokane, Ireland, of fifteen deaths which occurred in the district, eleven had reached the following ages: 104, 101, 86, 80, 78, 75, 72, 68, 60, and 60 years respectively.

—Dr. Robert Koch has expressed himself strongly in favor of the present movement in Germany which proposes compulsory vaccination. He thinks the dangers of transmitting syphilis and scrofula are almost infinitesimal.

—A Baltimore Coroner's jury found in the case of a colored woman recently, that she "came to her death from natural causes—cramp colic, produced by eating sausage for breakfast—and, in the opinion of the jury, the sausage was good."

A BON MOT OF ARAGO'S.—"What are comets made of?" asked a French lady of the distinguished *savant*. "Madame, I do not know." "Then what is the use of being an Academician?" "Madame, that I may be able to say I do not know."

—Dr. Elliott, of New Haven, says that when a diagnosis is uncertain, few doctors hesitate to tell a man that he has malaria. Again: "Medical men are almost superstitious in regard to the invisible spectre, malaria. One hardly dares to treat an obscure case without working in a good dose of quinia during the first day or two."

—Dr. Farquharson, M. P., speaking at the Scottish Educational Congress in Aberdeen, strongly condemned the effect of the present system of teaching upon the health of children, and urged the appointment of medical inspectors of schools, whose duty it would be to watch over the health of the pupils. The professors and leading educationists approved and supported this view.

—Dr. Langer states that the fat of a child "contains less oleic acid, but more palmitic and stearic acid than that of adults, besides being richer in the butyric and caproic acids." Perhaps that is what causes the infant to yell so vociferously during the night, but we cannot always tell. It may be the richness of the butyric and caproic acids, and it may be a displaced pin.—*Norristown Herald*.

—It is announced that the Johns Hopkins Medical School of Baltimore will be opened next fall. This institution is expected to be on a superior plane to any other now in existence in America—its course of instruction far more thorough, its degree correspondingly more difficult of attainment; at least seven years of study in all will be required.

OBITUARY NOTICES.

SIR JOHN FORSYTH, C. B., K. C. S. I.

Sir John Forsyth, C. B., K. C. S. I., late Principal Inspector-General of the Indian Medical Department (Bengal), and Honorary Physician to the Queen of England, died recently at Brighton, in 84th year of his age. The deceased was nomi-

nated a Companion of the Order of the Bath (civil division) in 1862, and a Knight Commander of the Star of India in 1881.

DR. WILLIAM BOWEN BRINTON,

Of West Chester, Penna., died suddenly on March 7th, of acute rheumatic fever with cardiac and renal complications. He was born November 30, 1842, and was the eldest son of the late Dr. John B. Brinton. He graduated in 1863 at the University of Pennsylvania, and in the same year entered the army as an assistant surgeon in the Thirty-third Regiment (Fourth Reserves). On May 3, 1864, he was promoted to the rank of surgeon in the One Hundred and Eighty-fourth Regiment, Infantry, of Pennsylvania Volunteers, and was mustered out with the regiment on July 15th, 1865. He was president of the Chester County Medical Society, and physician to the Chester County Prison, having succeeded his father, who was the physician for twenty-eight years. He was resident physician of the Pennsylvania Railroad Company, a vestryman in the Church of the Holy Trinity, was one of the active members of the Episcopal church, and a Master Mason. By his death the profession in Chester county loses one of its most active and promising members. He was married in 1871, to Miss Ida P. Futey, and leaves two children.

QUERIES AND REPLIES.

Dr. J. E. H., of Tenn.—Your letter was delayed through incomplete postage. In reply to your inquiry, we can only repeat what we have often said, that for physicians to bid against each other for public medical positions is an injury both to the public and to the profession.

Dr. T. J. W., of N. C.—Pure kerosene ought not to have an irritating effect either on the skin or mucous membrane. We have recorded instances in this journal where it was given infants by the spoonful, without injury.

Dr. T. W. E., of Ohio.—If any folly is the last, it is that of consulting clairvoyants by sending them locks of hair. Yet it is far from uncommon throughout this country.

Please inform me through your columns how perman-ganate of potash can be made into pills. Drs. Ringer and Murrell, of Paris, recommend it in the treatment of amenorrhœa, and prefer it to be given in pill form.

S. C. TRIPP, M. D.

Ans.—Pills can be readily made by powdering the perman-ganate and working up with a little powdered liquorice and a drop of gum arabic.

MARRIAGES.

ARMSTRONG-BLAIR.—On Wednesday, February 28, 1883, by the Rev. R. B. Foresman, Milton N. Armstrong, M. D., of Blairstown, N. J., and Lizzie K. Blair, of Johnsonburgh, N. J.

MCCURDY-JENNESS.—In Slate Hill, Pa., February 8, 1883, by Rev. D. M. Davenport, assisted by Revs. T. M. Crawford and Alfred Welles, W. H. McCurdy, M. D., and Laura J. Jenness.

DEATH.

DE LUNA.—In New York, on Friday, March 2, 1883, Abelardo R. De Luna, M. D.

J. C. Baker & Co.'s Cod-Liver Oil.

Absolute Purity and Freshness

Secured by Specifying our Brand

Prepared on the Halten Islands, Norway, with great care, from the finest selected livers of net-taken Cod Fish, at a season of the year when they are in their highest condition. Prize Medal, Paris, 1878; Berlin, 1880.

BAKER'S EMULSION,

With Hypophosphites of Lime and Soda, containing fifty per cent. pure oil, is a perfect and potent preparation.

We employ Baker's Cod-Liver Oil in preference to all others. The pure oil is palatable and digestible, and the Emulsion is well nigh delightful.

SOME CASES SHOWING THE EFFICACY OF ANTISEPTIC TREATMENT IN PUERPERAL DISEASES AS THEY OCCUR IN PRIVATE PRACTICE.

BY J. H. VOIGT, M. D.

Of Fredonia, Wisconsin.

CASE 1. Mrs. J., farmer's wife, age 30, multipara, was delivered of a healthy child May 8, 1882, by a midwife. Patient had the week previous a mild attack of scarlatina, the eruption having just faded at delivery. Had a slight chill on the 9th; a severe one on the 11th. Am called in to-day, the 12th. Patient is restless, and has an anxious, sunken expression; complains of thirst and pain in all bones. Skin hot and dry. Has a little pain over the region of the womb. Bowels loose and tympanitic; urine highly colored; vagina hot; womb large and a little tender; lochia foetid. Pulse 120. Respiration 32. Temperature 104. Diagnosis: Endometritis with septicæmia.

Ordination:

R. Quinæ sulph.,	℞j.
Acid muriat. dil.,	℞ij.
Acid carbol.,	gtt.xxiv.
Aquæ font.,	℞viij.

M. D. S.—Every three hours a tablespoonful in daytime.

At 8 p. m., quinia sulph. gr. x, and of the following mixture two tablespoonfuls to a pint of warm water as a vaginal injection three times a day:

R. Acid carbol. liq.,	℞ss.
Tinct. iodinii,	℞ij.
Aquæ font.,	℞viij. M.

May 13. Pulse 108, respiration 28, temperature 103. Patient has had no chill since the 11th; bowels are a little loose and tympanitic yet; urine high colored; had a little delirium in the evening; other symptoms as before.

Ordination: The same as yesterday, with light, nourishing diet. Leave 10 grain quinine powders for two days.

May 15. Pulse 112, respiration 36, temperature 101. Patient passed a comfortable day yesterday; has been a little delirious during first part of night, but has slept well since midnight for the first time; is very weak; has not much appetite; not much thirst; general appearance a little better. Bowels a little loose yet, and more tympanitic, as before. Urine high colored; no albumen.

Ordination: Give in the mixture, in place of water, French cognac, and order a turpentine stupe. Quinine powders the same as before.

May 17. Pulse 100, respiration 36, temperature 101. Patient feels better, has some appetite, sleeps well nights, has had no more chills since the 11th, mind clear, expression of face more natural. Bowels move once a day, urine clear, there is no pain on pressure over the womb, hardly any discharge from vagina, no fœtor, a little tympanitis yet.

Ordination: Mixture only to be given 4 times a day, another turpentine stupe and quinine powders as before, with nourishing diet.

May 19. Pulse 90, respiration 28, temperature 101. Patient is cheerful, expression of face natural, has appetite, sleeps well, absolutely no tenderness anywhere, no more chills, urine normal, bowels move twice a day—yet some tympanitis.

Ordination: Mixture and powders as before.

Vaginal injection once a day, one more turpentine stupe.

May 21. Husband comes to my office and reports patient much improved; has appetite and gains in strength. Discontinue quinine powders in the evening, also the mixture, and give in place the following:

R. Quiniae sulph.,	gr. x.
Tinct. ferri muriat.,	
Tinct. digital.,	
Potass. chlorat.,	āā ʒ ij.
Syr. simplicis,	ʒ ij.
Aquæ font.,	ʒ viiss.

M. D. S.—Every 4 hours a tablespoonful; continue vaginal injections once a day.

May 26. Pulse 72, respiration 28, temperature 98½. Patient feels perfectly well, has been freely desquamating the last few days (the first time since her attack of scarlatina), and is now slightly perspiring. Discontinue all treatment, and order good care and nourishing diet.

CASE 2. Mrs. D., farmer's wife, age 28, multipara, has been delivered by a midwife 3 weeks previous to my visit.

June 7, 1882. Had a severe hemorrhage from the womb a week after delivery, began to feel hot after that, and had a slight chill yesterday. Present condition: Patient is very anæmic, has great thirst, no appetite, and is otherwise indifferent. Some tympanitis, womb large, painful on pressure, with a deep bilateral laceration of cervix and foetid discharge from vagina. Pulse 120, respiration 30, temperature 105. Bowels regular, urine high colored, no albumen.

Diagnosis: Same as in first case, here probably due to retained decomposing shreds of membrane, or infection through the laceration in consequence of the filthy habits and surroundings.

Ordination:

R. Quiniae sulph.,	gr. viij.
D. tal. dos. No. iv.	

S.—1 powder morning and night.

R. Acid. carbol.,	gtt. xx.
Quiniae sulph.,	gr. xv.
Tinct. digital.,	ʒ ij.
Aquæ font.,	ʒ iv.

M. D. S.—Half a tablespoonful every 4 hours; and as a vaginal injection 30 drops of carbolie acid to a pint of warm water 3 times a day; besides apply a cornmeal poultice over abdomen, and give light nourishing diet.

June 9. Find patient very weak yet, but feels better; had a slight chill this morning, and has vomited twice during last night. Not much tympanitis; bowels regular; urine yet high colored.

Ordination: Medicine, same as before; discon-

tinue poultice and give a glass of Bordeaux three times a day.

June 10. Patient has greatly improved in every respect; womb is much smaller, and almost without tenderness to pressure and touch. There is very little discharge from the vagina, with but little smell; sleeps well; has some appetite; perspires some; urine normal; bowels constipated; no more chills. Pulse, 86; respiration, 22; temperature, 99.

Ordination: Continue quinine powders for two days and mixture for one week, three times a day, one-half tablespoonful; injection once a day. For the bowels, Species St. Germain.

June 15. The husband reports his wife gaining slowly; has yet but little appetite; bowels regular; some discharge from vagina, and is coughing.

Ordination: Discontinue quinine powders; continue injection once a day; give Bordeaux and the following mixture:

R. Quiniae sulph.,	ʒj.
Apomorphiæ hydrochloric,	gr. ij.
Acid. muriat. dilut.,	gtt. xv.
Potass. chlorat.,	ʒ j.
Syr. simplicis,	ʒ ij.
Aquæ font.,	ʒ vj.

M. D. S.—Every four hours a tablespoonful.

June 24. Husband reports his wife improved in every respect; has good appetite; bowels regular; has but little discharge from vagina, without smell; has no cough; sleeps well, but sweats very much and is weak.

Ordination: Discontinue all former medicine, and give only the following mixture, with nourishing diet and wine:

R. Quiniae sulph.,	gr. xv.
Liq. ferri sesquichl.,	ʒ j.
Tinct. belladonnæ,	ʒ ij.
Syr. simplicis,	ʒ ij.
Aq. font.,	ʒ vj.

M. D. S.—Three times a day a tablespoonful.

August 1. Patient is well, and soon ready for an operation.

CASE 3. Mrs. G., multipara, age 36. Was called June 29, 1882. Learned from husband that patient had been two months pregnant; began to flow after some hard work on the 24th; found small pieces in the clots on the 26th, when the hemorrhage almost ceased; had, on the 27th, two light chills and a severe one yesterday.

Present condition: Patient very weak and uneasy, with hot, dry skin and sunken features. Temperature 105, pulse 112, respiration 36; bowels confined; foetid discharge from vagina; on examination find most of the ovum within the os;

introduce speculum at once and remove all of it per uterine dressing forceps, after which wash out the womb per Davidson's syringe with rectum nozzle attached, with one pint warm 10% carbolic acid solution; after which put patient in bed and give a spoonful brandy and 10 gr. calomel and jalap, to be followed by a saline cathartic if necessary.

Ordination:

R. Quiniae sulph.	gr. x.
Tinct. gentian. comp.,	3 j.
Acid. carbolic,	gtt.xxv.
Aq. font.,	3 viij.

M. D. S.—Every four hours a tablespoonful, to begin four hours after administration of calomel.

Morning and evening gr. xv of quinia sulph., and as a vaginal injection a pint of 10% carbolic acid solution twice a day; besides, nourishing diet and brandy.

July 1. Find patient almost well, only very weak; looks cheerful. Temperature 99, pulse 80, respiration 19. Discontinue quinine powders; have mixture continued for three days and injection (5% solution) for one week.

July 5. Husband reports his wife well.

CASE 4. Was called in consultation by Dr. Smitz to see Mrs. R., October 20, 1882. When I arrived the doctor had left, leaving a note that I should examine case and proceed. Learned from husband that patient had aborted at third month four days ago; had since lost an immense amount of blood, and had flowed just previous to my arrival. Present condition: Patient multipara, 30 years old, farmer's wife, is profusely sweating and very weak. Pulse very rapid and hardly perceptible. On examination per vaginam, find part of placenta in the os externum; made an attempt to remove it, but patient fainted profoundly; after her revival introduced tampon; ordered good wine and beef tea, and left note for Dr. S. to meet me next morning.

October 21, a. m. Meet Dr. S.; find patient a little stronger, had a good night's rest. Temperature 102; removed tampon, found placenta in same position, womb very tender; introduced speculum and removed as much as possible of the placenta, but could not get all, as the womb had contracted very much, and the woman was almost again fainting. We could not attempt to wash out the womb on account of the narrowness of the canal and the prostration of the woman, therefore ordered only vaginal injections of a 5% carbolic acid solution, wine, nourishing diet, and the following mixture:

R. Quiniae sulph.,	gr. x.
Tinct. digital,	5 ij.
Spirit. frumenti,	3 viij.

M. D. S.—Every 4 hours a tablespoonful.

Dr. Smitz was to continue the treatment.

October 25, 4 a. m. Was called in haste to see patient. On arrival found patient with sunken features, profusely perspiring, very hot and almost pulseless, with a cadaveric smell about the room. Learned that Dr. Smitz had not been called in again—reason, because he is not married (the people are very ignorant); that patient had just passed out of a prolonged severe chill, of which she had had four the two previous days. There had been nothing done for the patient; even the injection was not used since my last call on the 21st. Gave hot brandy, applied hot bottles to the feet, and when patient had a little recovered, introduced double current catheter in the womb and washed it out with 10% carbolic acid solution, after which I washed out the vagina with a permanganate of potassa solution, which effectually stopped the bad odor. The womb was large and tender. When I left, the temperature was 106. On returning in the evening found patient a little better, pulse 130, temperature 104; again washed out the womb per catheter with same solution, gave 10 grains of quinine at once, and left gr. x of Doyer's powder for the night, because patient had not slept any for the last three nights.

October 26. Found patient much improved; had slept well during night; had had no more chill; had sweated very much during first part of the night. Temperature, 100; pulse, 110. Washed out the womb through catheter with same solution as before; ordered a pint of 10% carbolic acid water as a vaginal injection twice a day, and left the following mixture:

R. Quiniae sulph.,	gr.x.
Acid. carbolic,	gtt.xxiv.
Tinct. digital,	3 ij.
Aque font.,	3 viij.

M. D. S.—Every three hours one-half tablespoonful, and gr. x. quinia sulph. to be given at bedtime.

I did not give the mixture before, because the patient was in a moribund condition, and could not take anything but stimulants.

October 27. Found patient cheerful and laughing. Temperature, 99; pulse, 100. Some discharge from the womb, with very little smell; no tenderness; bowels and urine normal. Washed out the womb once more, ordered mixture to be continued as long as it would last, and had the vaginal injection with 10% carbolic acid solution continued for one week.

October 31. Husband reports his wife entirely well.

CASE 5. Mrs. F., primipara, age 21. Was called October 25, 1882, at 3 a. m., to attend patient in her first confinement, and she was delivered of a healthy male six-months child at 5 a. m. I did not detect anything unusual about the mother; therefore gave the usual directions and left.

October 30. Was called to see patient, who complained of much pain about the vulva. On examination, found the labia majora and perineum a little swollen and painful to the touch, with a fetid smell about the lochial discharge. On slipping my finger in the vagina, I found, to my surprise, a buttonhole opening, one inch long, in the floor of the vagina, with a nice reservoir for the lochia, etc., behind it, having no communication with the rectum nor with the outer world through the perineum, therefore a rent of the mucous covering and the fleshy parts of the perineum only. This had entirely escaped my attention at the delivery. As there were no other bad symptoms present, I washed the pocket out with a 10% carbolic acid solution, covered the raw surface with iodoform ointment, and filled the receptacle with lint; gave gr. x. of quinine, and ordered a vaginal injection of one pint carbolic acid solution (10%) twice a day. The husband was to report when bad symptoms should set in.

November 4. Husband came and stated that his wife was not getting along very well; that she had the ague for the last three days, and that the chills were always coming harder. I hurried to the place, and was sadly impressed when I found my robust and healthy patient from before so completely changed. The patient had passed through a severe chill two hours previous; she was therefore much prostrated, had lost much flesh, had a wild look about her eyes, and her features were sunken. She was only partially rational, and there was an almost unendurable stench about the room. Temperature 106, pulse 130, some looseness of bowels; water high colored. On examination found the swelling about the perineum, etc., had subsided; there was no pain, and the wound was beautifully granulating (due to the iodoform ointment). But the vagina was hot, and the womb hard, much enlarged, very tender, and quite immovable; lochia fetid. Patient also complained of very much pain in both legs, which were also tender to the touch, but not swollen. She had besides great thirst, and no appetite; the lacteal secretion had stopped.

Diagnosis: Septic endometritis with a prospect

of metrophlebitis and speedy resolution (death). But all this was no wonder, as the vaginal injection had been omitted since my last call, and the neighboring old women had kept the bedroom close and hot, had also administered plenty of hot tea, and had covered the poor woman with two featherbeds in order to cure the ague! Only the iodoform salve had been used, but of course the infection had extended upwards before the iodoform was applied. I at once opened the windows, had the fire put out, and had bed and patient cleaned; then washed out vagina with one quart 10% carbolic acid solution, applied a cornmeal poultice to the abdomen, rubbed the legs with ext. belladonna in olive oil, wrapped cotton about them, and laid a pillow under each leg. Then gave gr. xv quinia sulph. in brandy, ordered injection strictly to be repeated in the evening, beef tea and brandy, and left the following mixture:

R. Quiniæ sulph.,	℥j.
Acid. carbolic,	gtt. xxv.
Tinct. digital,	℥ij.
Tinct. opii simpl.,	℥j.
Aq. font.,	℥vijs.

M. D. S.—Every 3 hours 1 tablespoonful.

November 5. Find to my great joy patient improved. Mind clear, tongue moist, a little appetite, but no sleep; bowels had moved once. There is yet much tenderness about the womb, some tympanitis, and legs are also painful yet. Discharge from vagina is fetid and quite abundant; had one more chill. Temperature 102, pulse 120. Left 2 quinine powders, each gr. xv., for two days; had vaginal injection strictly continued twice a day, the above mixture to be given every 4 hours; extract belladonna, etc., reapplied to the legs with cotton and roller, and ordered nourishing diet with good wine and a fesh poultice to abdomen.

November 7. Patient is greatly improved, has appetite, rests well, not much thirst, bowels move once a day, lacteal secretion is re-established, there is very little tenderness about the womb, but some discharge. The laceration of the perineum is almost healed; she has no more pain in her legs, and had no chill. Temperature 99, pulse 90. Have the vaginal injection continued once a day for one week, and also the following mixture:

R. Vini cinchonæ,	āā ℥ij.
Tinct. gentian. comp.,	℥ij.
Acid. muriat. dilut.,	℥ij.
Aquæ font.,	℥iv.

M. D. S.—Every 4 hours a tablespoonful.

Left two 10 gr. quinine powders for the next two days, with directions about food, etc.

November 11. Husband reports his wife well.

Had in this case my orders about the vaginal injection, etc., been faithfully carried out, I am convinced the patient would have gotten well without further trouble. In the country we cannot sometimes see our patients as often as necessary.

CARIES OF THE SUPERIOR MAXILLA.

BY JOHN S. SMITH, D. D. S.,
Of Lancaster, Pa.

John B., an attorney, aged 58 years, nervous bilious temperament, strumous diathesis, residing in the city, came to me in January, 1880, suffering from pain in the left superior molar, caused by the recession of the gums about the palatine and buccal roots. The usual treatment was applied, and the patient instructed to call again in a day or two.

At the next sitting, at his suggestion, a careful examination of the teeth were made. The dark appearance of the right superior canine and lateral incisor teeth arrested my attention; the gums around these teeth were hypertrophied and spongy. An opening about three lines from the margin of the gum and between the fangs of the teeth, on the labial aspect of the alveolar process, was noticed, from which a thin ichorous fluid escaped when pressure was made on the gum above the sinus. At this point of the examination, the patient remarked, "that the discharge was more or less active for a number of years, but as there was no pain, he paid no attention to it."

Caries was not extensive in these teeth. The cavities had been filled with gold several times during the past thirty years; these I removed, and found the pulp chambers and canals empty and dry. The teeth were dead and slightly loosened in their aveoli, the septums of which were partially absorbed. Has had periodontitis; the face would swell and then the swelling pass away.

Diagnosis.—Caries of the jaws may be confounded with other affections of the same bones: alveolar dental abscess, necrosis, diseases of the antrum and carcinoma. How may alveolar dental abscess be distinguished from caries and necrosis?

The distinguishing of alveolar abscess from caries and necrosis would at first seem somewhat difficult; each condition is dependent upon dead tissues, and both have sinuses leading to them. In alveolar dental abscess there will be noticed an absence of that inflammatory deposit which is so constant around dead bone. The sinus will be short, and single, and the pus issuing therefrom

nearly inodorous. In caries of the bone the probe can be driven into it, owing to the soft, spongy, honey-combed nature of the tissues. It is extremely important that a correct diagnosis be made, since the treatment of the two diseases is so radically different. In alveolar abscess, the tooth is to be removed or treated; in caries, we are to expedite the arrest of the morbid process; in necrosis, to delay until separation of the sequestrum occurs.

A sequestrum thrown off from the body of a bone may lodge and be retained in the soft parts, keeping up a discharge long after the acute inflammatory condition may have passed away. These retentions of sequestra are very common in clinical experience.

In this condition the sequestrum will be readily discovered by the probe. A piece of dead bone feels to the probe like a piece of hard wood, differing thus from the healthy bone, which is obscured by its periosteum; and differing also from the dying, sloughing bone of caries in the absence of the pitted, soft, irregular face which always marks this latter condition.

Where there is a soft condition of bone like that of caries, how may we distinguish the lesion from the sloughing bone of cancer, or the neoplasms or non-explainable tumors of the jaws? A probe may be passed through an ulcer upon the gum, and carious bone be met at every thrust of the instrument; the ulceration may be so slight as to command scarcely more than a passing thought, and yet it may prove a malignant disease. An intelligent conception of such disease through a process of exclusion would in all probability save life, or at least a long train of evils would be avoided. Half-medication, or superficial surgery to what may be primarily a benign lesion, will in all probability end in malignancy, and death of the patient. We see striking illustrations too often to corroborate the fact.

All self-explainable disease, whether of local or systemic signification, possesses in itself the meaning and manner of cure, and is treated on a purely scientific basis; "cause is understood, cause is managed." When studied from a clinical standpoint, age, history, diathesis, cachexia, pain, destruction, rapid or slow growth of the diseased tissues, all have their value in determining the real nature of an obscure disease. Aside from the physical symptoms, the histological classification of diseased tissues, as revealed by the microscope, is a great factor in the study of morbid structure, and invaluable in making the diagnosis.

Pathology.—According to some authors, there are but two forms of actual ulceration of bone, called caries—the one simple, the other fungous caries. Other equally eminent authorities say caries, practically viewed, is possessed of the three-fold expression—simple, strumous, and specific. Simple caries corresponds to what, upon the skin, we would call an indolent ulcer. The jaw bones are peculiarly subject to this disease; and of the two bones the superior maxilla is the one most affected, the reason of which has, we believe, as yet not been given.

The most prolific cause of the disease is the retention of dead teeth and roots of teeth; other causes are assigned, but the former by far preponderate. In simple caries of bone, a loss of substance at the surface of a bone is said to be slowly growing deeper upon the whole, however shallow, upon whose base small amounts of pus, together with broken-down remnants of tissue, continually appear. This result is produced by the exposure of medullary tissue. At a certain distance from the surface it is in a hyperæmic, hyperplastic condition, which, according to our best pathologists, gives place near the surface to an extraordinarily dense cellular infiltration.

The cells completely fill all the pores of the osseous structure, the blood-vessels are compressed, and then, together with the cells, themselves go over into molecular detritus.

This form sets in as soon as the cartilaginous coverings are definitively destroyed; the bone now projects uncovered into the cavity filled with pus, and communicating with the air by one or more fistulous openings. The small fragments of bone are loosened simultaneously with the detritus which envelops them. They can be felt like grains of sand in the thin ichorous pus which the articular cavity secretes.

These developments are but guides to a correct diagnosis.

Having diagnosed the above case to be caries of the strumous expression, the treatment was as follows:

Local Treatment.—The dead canine and lateral incisor were removed. All debris was now washed away, and a stimulating and antiseptic treatment adopted; the preference was given to the tincture of iodine in combination with carbolic acid, one of the acid to twelve parts of water, the parts syringed about three times a week for two weeks. The carbolized treatment was then dropped, and chloride of zinc, alternated with the aromatic sulphuric acid, was used, and the sinus thoroughly syringed daily with water. At

the end of four weeks the secretions are not so copious, and not so offensive.

The zinc treatment was strictly adhered to. At the end of about four months a marked improvement was noticeable in the character and flow of the secretions, but no preceptible signs of granulation could be noticed. Nature, with all the aid given, seems unable to throw off the incubus of the disease, there being a low condition of vitality and a marked anæmic condition of the patient.

Treatment continued one month longer. Tincture of iodine, diluted, was now used every other day, with favorable result; patient encouraged; the soft parts look much better. It was now decided to use the burring engine, and to bring the parts into better view. A V-shaped section of gum was removed, exposing a cavity of large size in the superior maxilla. A sharp burr, selected and made to revolve at a high rate of speed, cutting in the direction where the probe detected deterioration of substance, or roughened condition of surface: the operation was repeated three times at intervals of from three to six days, washing the parts thoroughly after each operation with tepid water, and the surface carefully wiped over with aromatic sulphuric acid. The acid treatment was kept up at longer intervals, until granulation could be felt with the probe: the cavity slowly filling from within outward, which condition could be easily felt with a blunt instrument.

The cavity in the bone having nearly closed, the break in the continuity of the soft tissues still remained open. To get the edges to approximate was the next step in the treatment; as this could not be accomplished in the ordinary way by stitching, it was decided to use the nitrate of silver, a suggestion of my friend H. B. Stehman, M. D., to whom I had shown the case. A small quantity of the nitrate of silver was placed in a glass test-tube, which was melted over a spirit lamp. A thin silver wire was now selected and dipped into the nitrate of silver. By this means the nitrate of silver was carried to the bottom and edges of the opening until it closed by granulation.

General Treatment.—This was of a tonic and supporting kind, the chalybeates having the preference. Plenty of out-door exercise, together with good nourishing food, was enjoined. Patient made a complete recovery, and was dismissed cured in nine months. No return.

We might here add that the patient had several fistulous openings upon the side of the neck a number of years previous; and subsequently was similarly affected upon the same side of the jaw, at this time losing the bicusps and first molar.

Clinically, the case is one of more than ordinary interest. It shows slowness of these chronic cases to yield to treatment after being so long neglected, especially when the strumous diathesis is present, and the general tone of the system low.

HEALTHINESS OF WASHINGTON CITY—MALARIAPHOBIA.

BY I. B. JOHNSON, M. D.,
Of Washington City, D. C.

Of all the names of the causes of disease, that of malaria has been the most misapprehended and most abused. The diverse and multifarious symptoms ascribed to its poisonous effect have been myriad; and however and whenever an individual is taken sick, malaria is reviled and derided as the cause of such sickness. This general belief of the unlimited prevalence of malaria in the excitation of disease in the District of Columbia has placed it high in the popular mind as the cause of nine-tenths of the ill-health that afflicts the community. Therefore, every one interested in the prosperity of the City of Washington should feel a great desire to have a rational attempt made to disabuse the popular mind of this most unjust and injurious impression, and to acquit the reputation of Washington city of the imputation of being an exceedingly malarious place; for this false charge, based upon erroneous impressions, has gone forth throughout the United States, much to the injury of the business interests of the city; and the timid-minded stranger possessed of this *maliariaphobia* is absolutely afraid that if he visits Washington city he will be at once infected with malaria, and either return home sick, or be carried back dead. It is not a supposition, but a prejudicial and serious fact, that a firm impression has obtained abroad that Washington is a very unhealthy city. The question is, how has this erroneous misapprehension obtained such an influence over the public mind, without sufficient testimony to sustain it? Much of this is due to the complaints and expressions, within and without the medical profession, of Washington's own residents. For the last five or ten years, it has been an unvaried fashion to call every slight cold, every case of hectic fever, the effect of every debauch, and every derangement of the body, "malaria," and malaria has thereby been made the *hocus-pocus* in the play of every deviation of the general system from a healthy standard; and quinine, the antagonistic, has grown into a fashionable *abracadabra* of every ache and pain, in

many instances to the detriment of the ill-informed and badly-advised victim of the delusion; but fashion spreads by imitation, and as the District of Columbia has tenaciously kept up the fashion of calling every temporary disorder of the body the effect of malaria, it is not surprising that strangers, hearing so much about the suffering attributed to malaria, should conclude that Washington city is a very *malarious* locality. It is in this way that malaria has been popularized, and the conceit has arisen that to be sick from any other cause, and not be able to boast of having taken large doses of quinine, would be apparently out of fashion.

COMPARISON.

The District of Columbia has a population of one hundred and eighty thousand. Of this population, forty thousand are colored; and it is familiar to sanitary officers that the colored population is not as well provided for, in a pecuniary relation, against the influence of disease, as the whites. This accounts for the difference in the mortality of the two races. New York, Brooklyn, St. Louis, Baltimore, Cincinnati, Jersey City and Pittsburgh, are seven of the principal cities of the United States. They represent a population of over three millions and a third, and have an annual death rate for total deaths of thirty-three and twenty-two hundredths per thousand of their population, while the District of Columbia has only an annual death rate for total deaths of twenty-eight and sixty-nine hundredths to the thousand of its population, thus showing by a comparative average that the chances of longevity stand four and fifty-three hundredths greater in the District of Columbia than within the population of the cities named. In view of this comparison, one is apt to conclude that it ill becomes the correspondents and editors of the newspapers of these respective cities to unjustly represent the District of Columbia as an unusually unhealthy and malarious locality; and in conclusion it may be safely declared that Washington city is not, in a sanitary sense, unusually malarious, and that not four of the ten cases of so-called malarial diseases of the city are, either directly or indirectly, excited or influenced by malaria; and, finally, medical experience has proved that the effect of malaria has been slowly and surely diminishing in the District of Columbia for and during the last ten years. This fact makes it a safe declaration that no city in the United States presents, as an abiding place, superior advantages to Washington city in morality, salubrity, quiet and intelligence

A REMARKABLE TOLERANCE OF OPIUM.

BY GEORGE P. YOST, M. D.,
Of Loganville, Pa.

The subject of this sketch is a man, single, aged about 25, tall, angular, dark hair, the motive temperament predominating, and subject to a peculiar "nervous trouble traceable to heredity." He commenced a life of debauchery, becoming intoxicated frequently, and using tobacco to excess, at the age of sixteen years. This he continued till about three years ago, when he suddenly reformed, using no stimulants—except tobacco—and going to work with all earnestness, and apparently deeply regretting his former career.

This lasted about two and a half years, when he gradually lost interest in his business, and commenced the opium habit.

The "nervous trouble" alluded to, which began at about the age of fourteen, comes on by "spells," or periods of attacks, without any regularity. Sometimes the patient has an attack every week, then again none for a month or longer; nor do they have any regularity of continuation, sometimes lasting twelve, twenty-four, and on to seventy-two hours. They come, as a rule, suddenly, without any prodroma, and disappear in the same manner.

The nature of the attack is *loss of motion of all parts of the body controlled by the spinal nerves*.

Respiration, deglutition, speech, the heart's action, the generative and urinary functions, are not impaired, but the bowels seldom move during an attack. As already stated, these attacks come suddenly, often during sleep; the patient going to bed in his usual good health, and on awaking in the morning finding himself unable to move. In the same manner do they leave. Sometimes the patient, being entirely powerless, suddenly begins to feel returning power in the fingers or toes, which extends gradually—and within an hour he is able to "take up his bed and walk," feeling none the worse for his enforced rest.

These attacks are traceable to the *male* portion of one entire family; and to most of their *male* offspring; the *female* portion of the family and their *female* offspring being subject to attacks of "sick" or nervous headaches. Neither males nor females are attacked before puberty. As it is not the object of this article to discuss the etiology or pathology of these attacks, I will leave that for some other time, hoping that in the meantime this short sketch of this very peculiar affection may catch the eye of some of our neurologists who may be able, and will throw some light on it.

In February or March, 1882, the subject of our sketch commenced to use small doses of opium—being a veterinary surgeon, he knew its dose and effects—to enable him to "sleep off those spells," as he expressed it, and soon found that it would cut them short. Soon he commenced to take the opium at the beginning of the attacks, and found that he could abort them, and that the regular use of the opium prevented their return.

But lo! the habit soon increased on him; and, without trying to resist it, he soon became a regular opium habitue, using first one, then two and more oz. of *tr. opii*. (U. S. P.)—this being the form in which he used it—until within nine months time he consumed as high as *ib.j. tr. opii per day*.

This he continued till December 31, 1882, when by drinking whiskey with it he ended with a regular debauch, when he so demeaned himself before his friends and the public that he became deeply mortified, and made up his mind to stop it, which he did, and has up to this date (March 5, 1883,) not taken a drop—no stimulant, in fact, with the exception of a few drinks of whiskey one day about two weeks ago, which led to slight intoxication.

He seems to suffer no inconvenience from his sudden breaking off, except a slight insomnia. He continues the use of tobacco, but takes no medical treatment.

The remarkable phenomena of the case—to my mind—are the rapid increase of the opium; the remarkable toleration by the system of said increase, for he suffered no inconvenience from its use while using it, except some constipation; and the sudden breaking off without any apparent inconvenience.

The remarkable career of this patient, together with his family history, should be interesting to neurologists, as well as to those who make a special study of inebriety and *opium habitues*.

CONVULSIONS CAUSED BY PREPUTIAL IRRITATION.

BY C. POLLOCK, M. D.,
Of Muncie, Ind.

By request of parents I visited their babe in Dayton, Ohio, December 16, 1882, and received history as follows:

The babe is one of twins, born of healthy parents, of average size and good health up to the age of five months, when it suddenly had a convulsion and seemed slightly feverish, on October 25, 1882. It had convulsions at irregular inter-

vals from that date—some days having few or none, and others as many as twenty-two convulsions in the twenty-four hours. Between the convulsions it seemed bright, and nursed well and retained food, and all functions seemed to be normally performed. At the time I visited it the convulsions came on only upon awaking from sleep, the eyes fixed, pupils not dilated, and if spoken to his eyes are directed to and follow the speaker, and he does not seem to lose consciousness, but is unnaturally quiet for a few seconds and then strains terribly, so that he raises his feet and head six inches from bed. Becomes rigid and red in face, and invariably either urinates or defecates, and on relaxation of convulsion cries violently. He had been attended constantly from October 25th to December 16th by three irregular practitioners, together and singly by relays, and parents were assured that “the cause of the convulsions was indigestion, with reflex action on brain.” The parents called attention of attendants to generative organs, and were assured by them that there could be nothing wrong there, as the boy was a case of “natural circumcision,” about one-third of glans penis being exposed. I detached and slit up the prepuce and removed smegma of consistence of soft cheese, in amount to size of small pea, moulded to fit neck of glans, and found mucous membrane not broken; gave no medicine. Babe had several light convulsions up to the healing of cut surface, the last one occurring December 25, 1882, and improved in every way till about February 1st, when it had fever of malarial character and was attended by Dr. C. A. Humphreys, of 1421 E. 3d street, Dayton, O., and I am informed by him that during its recent illness the babe did not manifest as much nervous starting as is usual in babes of like age and grade of fever. I will gladly answer any questions relating to this case omitted for sake of brevity, and my readers can draw their own conclusions and apply the moral.

The Gospel of Fatness.

Thus writes Dr. Clouston:

“All acute mental diseases, like most nervous diseases, tend to thinness of body, and therefore all foods and all medicines and all treatments that fatten are good. To my assistants and nurses and patients, I preach the gospel of fatness as the great antidote to the exhausting tendencies of the disease we have to treat, and it would be well if all people of nervous constitution would obey this gospel.”

HOSPITAL REPORTS.

CLINIC OF J. A. LARRABEE, M. D.,

Professor of Materia Medica and Clinical Lecturer on Diseases of Children, Hospital College of Medicine, Louisville, Ky.

Tabes Mesenterica.

GENTLEMEN: This little fellow of seven years is presented, with the following history: He has been from birth a child about whom his mother has been solicitous because of his weakly constitution. He has had several of the diseases incident to childhood, such as varicella and whooping cough. Considerable importance attaches to the latter, not much to the former. Having, then, been a delicate child from birth, at an early age, his mother tells us, he had a lump on the side of the neck, which remained for a long time, but finally disappeared. About two years ago he contracted the whooping cough, and from it he has never fully recovered. He has now indigestion, distension of the bowels and diarrhœa, swelling of the feet, coldness of the extremities, and diurnal febrile disturbance, the chief source of anxiety to the mother being the swelling at times of the abdomen.

Perhaps the first point of importance in entering upon the consideration of a case like the one before us, is the age of the child. In previous lectures I have often insisted on the recognition of the fact that certain periods of childhood are critical periods. Not only the fatality, but the prevalence of diseases, is greater during the first dentition. That period of the child's life coincident with the eruption of the teeth is attended by very many disturbances dependent upon that process; for instance, in the summer season it has an influence in enervating the system, placing it in a proper condition to be more susceptible to the exciting causes of cholera infantum, diarrhœa, etc. In the winter the exciting causes of disease being of a different character, the resistance, however, being lessened by dentition, the child is then more likely to suffer from disorders of the respiratory system. Another period of crisis occurs when the permanent teeth displace the milk teeth, and the second, though less important, dentition occurs. Certain nervous disorders most frequently manifest themselves at this period, chorea being now particularly liable to occur, convulsions less so on account of the increased development of the will-power at this later age of the child.

The family history shows a not very perfect history of tubercle, the mother having been presented in another clinic, where a diagnosis was made of tuberculosis of the connective tissue investments of the turbinated bones. The father and mother are both living. I have not yet made a physical examination of the child, but my remarks apply to the case and the history as thus far presented. The probabilities are that we have here to deal with a malnutrition which will result in the deposition of tubercle, if it has not already done so, provided it be not arrested. This imperfect assimilation, resulting in emaciation, offers favorable opportunities for any underlying diathesis to manifest itself, and if there be any ten-

dency toward tubercle, it is likely to make its appearance. Hence, the danger of neglecting these diseases of the digestive apparatus. If the process of digestion is properly accomplished, and assimilation is perfect, we need have little fear of the deposition of morbid products.

The mother states that the child's abdomen is swelled considerably, and this statement is verified by the exposure of the child. Just here I want to caution you against a common error of too frequently pronouncing a diagnosis of *tabes mesenterica* in these cases. You are impressed with the idea, from reading many of the books, that "swelled-bellied children" (excuse the expression) are nearly invariably the subjects of *tabes mesenterica*. Nothing could be more erroneous than this, for nothing is more common in children than very large bellies. This is strikingly illustrated in the masterpieces of the old artists. In those ages their close observation taught them that very large abdomens were common among children. Thus the presence of enlargement becomes insignificant as an evidence of tuberculization of the mesenteric glands, unless it be accompanied by evidences of malnutrition. On the other hand, it is more common to meet with a shrunken abdomen, through the walls of which the enlarged glands may be felt around the navel, where they belong.

In the case before us I have no doubt that the tendency is to abdominal phthisis. The history of the child indicates it, its surroundings favor it, and examination confirms it. The child had whooping cough which lasted for months; its present decline dates from the beginning of that attack, since which it has been ill almost constantly. This is a significant fact, in the strumous subject very significant indeed. Whooping cough is attended by enlargement of the glands, especially the bronchial glands, and brings the association very close indeed to what is manifested here.

There is another factor here which cannot fail to attract your attention, as it cannot fail to arouse at the same time your sympathies, that these little ones must so soon realize the suffering of deprivation and want. This child you observe has nothing to protect him from the cold; no flannel, no woolen—in short, all of the first principles necessary to observe to prevent impoverishment of the blood cannot in this case be insisted upon, viz., warmth of the surface. If we can succeed then in a case like this, where we have to work against such odds, our success is a double triumph compared to that in private practice, where these things are regulated without our attention.

Now the case before us being one of tuberculization of the abdominal glands—a common form of tubercular manifestation in childhood—how are we going to arrest the process and effect a cure? These cases are not rapid in their course, indeed are not even uninterrupted, but are attended by periods of activity and repose, just as phthisis in other localities and varieties. In these cases we are guided by the dejections. At one period diarrhœa occurs, and then follows an interval in which the dejections are almost normal. Peritoneal pain occurs, passes away, and is forgotten until another attack appears. This also, when it occurs, means fresh activity and deposit of the tuberculous matter.

In the treatment we can take advantage of the periods I have mentioned to institute measures which will arrest the disease. I have in my mind now the case of an individual who came to this clinic when a child, seven or eight years ago. In the course of her treatment she took perhaps forty or fifty bottles of malt, and a great deal of cod-liver oil by inunction. She has now grown to be a young woman, and remains in a good state of health notwithstanding the fact that she had passed through an attack of typhoid fever. This is but one of many cases to show that we can arrest this process when here situated, as we can bronchial phthisis.

I wish now to interpose a remark here which I have purposely postponed until this time in order to impress it the more forcibly upon you. It is to warn you against an almost besetting sin, that is, the partial diagnosis of these cases as intermittent and remittent fever, without ever stopping to think that the febrile manifestation present every evening or morning, every day or every other day, instead of being a manifestation of malaria, may be a manifestation of tubercular disease. The very moment you grow careless in regard to the treatment of long continued fevers, where you have used quinine, Fowler's solution, and all the antiperiodics, you should rouse yourself to the importance of a physical examination. The compound terms so frequently employed to designate irregular manifestations of disease you will find to be superfluous, if you study to become acute diagnosticians; and, many times, such terms as typho-malarial fever indicate not a condition of the patient's body, but, on the contrary, a condition of the practitioner's mind. Be watchful, then; be careful; and if there be an underlying diathesis in such a case, find it out before some other is called upon to discover it for you.

To return, now, to the treatment. As I said before, in a case of early phthisis, the one thing to do is to secure a proper assimilation. So soon as we think of tuberculization of the mesenteric glands—indeed, for that matter, of any other manifestation of tubercle—we think of cod-liver oil. It seems to rise up in our minds almost as suddenly as it rises in the throat of him who swallows it. It presents itself because we think of it as a specific for consumption. In this case we have made our diagnosis; now let us base our treatment upon a knowledge of the pathological condition and the physiological function of the parts affected. The disease is here interfering with the introduction of food by absorption. How shall that be overcome? Shall we attempt it by the administration of cod-liver oil, or administer the hypophosphites with oil? If we do, we shall find they take the same course as other food. They will pass undigested, unabsorbed; emaciation will continue, and the child will go down. Such a plan throws discredit upon the agents used, because there has been an error made in the administration. In this case, then, I would use milk with pancreatin. This will be absorbed. Then, if you use cod-liver oil (it should be used by all means) use it by inunction. Rub it into the abdomen. There is that in the rubbing in of oil which stimulates the ultimate nerves and gives an impetus to nutrition. Then let this child be oiled, and have that oil rubbed in, and see how

soon he will begin to present a better appearance. Since he cannot have clothing sufficient to protect him as he should be protected, let us treat him somewhat on the Esquimaux plan. Then, besides this, in the extract of malt, we have a palatable preparation. Give it to the child three times a day, in conjunction with the other measures I have named, in the manner I have indicated, and in a week this child will have improved.

You see I have given no opiates to correct the diarrhœa. That would be wrong, for the diarrhœa depends upon indigestion. We will secure a better digestion by the treatment already described, and the diarrhœa will take care of itself. Last of all, we will endeavor to secure, through the coöperation of the mother, better attention to clothing and hygienic surroundings, and hope to show you the child at a future clinic in a better state of health.

PROCEEDINGS OF "THE COLLEGE OF PHYSICIANS OF PHILADELPHIA."

A Partial Study of the Poison of Heloderma Spectum (Cope)--The Gila Monster.

BY S. WEIR-MITCHELL, M. D., AND EDWARD T. REICHERT, M. D.

[Read February 17, 1883.]

(Continued from page 293.)

Experiment II.—In the following experiment a full-grown etherized rabbit was used, and the left carotid being connected with the kymographion, one-sixth of a grain of dry Heloderma venom, dissolved in one cc. of distilled water, was injected into the external jugular vein.

	1.35			Violent convulsions. accurately be counted.
				The animal died in convulsions with dilated pupils.

The results were identical with those obtained when the pneumogastries were entire, so that the effect on the heart is direct, and not by inhibition through the pneumogastries.

The results of the autopsy in both of the above experiments are identical, and may be summed up as follows:

Autopsy, Made Immediately After Death.—Heart arrested in diastole; heart does not react to induction currents; muscles everywhere respond to electric stimulation; motor nerves intact; cord unirritable, and will not respond to the strongest current produced by one large gravity cell, with Du Bois Reymond's induction coil; bowels still irritable; peristaltic movements occur spontaneously; the intestines are natural in color, as are all other organs. After five minutes the heart began to contract, and was finally found in a systolic condition. The interior of the organ was full of black clots, especially the auricles, the left ventricle containing but a very small clot.

In order still further to determine the effect on the heart, the following experiments were made:

Experiment IV.—

Hrs. Min.

7.33	Pithed frog and exposed the heart.
.52	Heart beats 21 in 30 seconds.
.52½	Placed a small portion of dried venom of Heloderma on the heart.
.56	Heart beats 20 in 30 seconds.
8.05	" " 19 in 30 "
.18	" " 18 in 30 "
.30	" " 15 in 30 "
.43	" " 14 in 30 "
.55	" " 10 in 30 "
9.30	" " ceased.

Experiment V.—

Hrs. Min.

8.05	Took two "cut-out" hearts of frogs, and placed them in a normal salt solution in separate vessels, just sufficient liquor being used to cover the hearts. On one heart was placed a small quantity of dried venom.
.27	The poisoned heart beats more feebly than the other.
.30	The poisoned heart beats still more feebly than the other, which is yet firm.
.45	The poisoned heart stopped beating, the other beats firmly.
.55	The poisoned heart stopped beating, the other beats firmly, but slower.

Experiment VI.—

Hrs. Min.

3.45	Exposed the hearts of two pithed frogs.
4.00	Placed on one some dried venom.
.30	The poisoned heart beats are decidedly feebler than the other.
.50	The poisoned heart beats more feebly; the unpoisoned heart beats firmly and apparently in a normal manner.
6.00	The poisoned heart beats very feebly and does not fill with blood. The normal heart beats firmly, and fills well with blood at each beat, making a striking contrast with the poisoned heart.

We may conclude that—

The poison of *Heloderma* causes no local injury.

That it arrests the heart in diastole, and that the organ afterwards contracts slowly—possibly in rapid rigor mortis.

That the cardiac muscle loses its irritability to stimuli at the time it ceases to beat.

That the other muscles and the nerves respond readily to irritants.

That the spinal cord has its power annihilated abruptly, and refuses to respond to the most powerful electrical currents.

This interesting and virulent heart-poison contrasts strongly with the venoms of serpents, since they give rise to local hemorrhages, and cause death chiefly through failure of the respiration, and not by the heart, unless given in overwhelming doses.

They lower muscle and nerve reactions, especially those of the respiratory apparatus, but do not, as a rule, cause extreme and abrupt loss of spinal power.

Finally, they give rise to a wide range of secondary pathological appearances, which are absent from *Heloderma* poisoning.

There remains on our minds no doubt as to the fact that the fluid which drips from the mouth of *Heloderma* when it bites is a very active poison. The present study is, however, limited in range, and we cannot yet feel sure that the fluid in question comes from the glands now presumed from their relation to the teeth to be poisonous.

The briefest examination of the lizard's anatomy makes clear why it has been with reason suspected to be poisonous, and why it poisons with so much difficulty. Unless the teeth are entire, the poison abundant, and the teeth buried in the bitten flesh so as to force it down into contact with the ducts where they open at the crown of the teeth, it is hard to see how even a drop of poison could be forced into the wounds. Yet it is certain that small animals may die from the bite; and this may be due to the extraordinary activity of the poison, and to the lizard's habit of tenaciously holding fast to what it bites, so as to allow time for a certain amount of absorption.

It is plain enough that a lizard as small as the one exhibited would be very unlikely to inflict a wound fatal to man; but it is possible that the larger animal—and it is said to reach a length of three feet—might prove a more efficient poisoner.

We are unwilling to drop the subject without a few words as to the nature of this poison.

The recent researches of Dr. Sternberg and Prof. Gautier have shown that human saliva may kill a rabbit in twenty-fours, and a pigeon in a few hours, if a quantity of saliva have been concentrated by heat and so used. Prof. Gautier thinks the saliva and all venoms owe at least a part of their power to normal ptomaines or animal alkaloids, the products of putrefactive processes, and recalls to us the fact that most secretions are measurably poisonous.

The answer to these views we shall have to consider elsewhere, and at length; but it will be sufficient here to say that there is no resemblance between the symptoms caused by the known ptomaines and those produced by any of the venoms. When it was shown that healthy human saliva was competent to kill, it was natural enough to

leap to the conclusion that the venoms were merely concentrated salivas. The analogy ends with the fact that both may cause death; but the one may kill in twenty seconds, and the other requires, at the least, many hours, whilst also it

seems, as regards saliva, to be, in some degree, a question of the toxic activity of certain individuals, not all being so uncomfortably endowed as Dr. Sternberg himself.

EDITORIAL DEPARTMENT.

PERISCOPE.

Abdominal Aneurism Rupturing into Psoas Muscle.

Mr. W. E. Bailey reports the following unusual case in the *Lancet*:

P. G—, aged forty-two, laborer, married, was admitted on May 23d, suffering from pain in both hips, back, and left side. His general appearance was that of a well-nourished man of muscular build. His previous health had been good until two years ago, when he fell from a scaffold, alighting on his back. After this accident he experienced severe pain of a gnawing character in the back and left lumbar region. The pain was constant, but subject to many severe exacerbations. Any attempt at progression increased its severity. No history of syphilis or chronic alcoholism.

On examining the seat of pain, no swelling could be detected, but the dullness in the region of the left kidney was abnormally increased in area, extending horizontally from the vertebral column behind to a point midway between this and the middle line in front, and vertically in the mid-axillary line from the ninth rib to a couple of inches above the crest of the ilium. Pressure over the area of dullness caused great pain, and when in the recumbent position, the patient experienced great difficulty in turning from side to side, during which effort the spinal column was kept quite rigid. Heart and lungs free from organic disease; pulse regular, quick, and moderately strong; anorexia; temperature normal; urine healthy. Palpation and percussion revealed no other abnormal peculiarities in other regions of the abdominal cavity. Turpentine stupes were applied over the painful part, and one grain of opium was given at night with great relief.

Patient appeared to be doing well until the 29th of May, when he again suffered from very severe gnawing pains, which were relieved for the time by the application of turpentine stupes. The following evening, the pain recurring in the left lumbar region, a hypodermic injection of amyl nitrite (1 in 10) was administered, and followed by almost immediate relief. Patient slept well during the night, and expressed himself as feeling much better the following morning, the pain having entirely disappeared. About this time (June 1st) the patient was placed on low diet and large doses of potassium iodide, absolute rest in bed being enjoined. He seemed to be progressing sat-

isfactorily until the evening of June 21st, when he became suddenly much worse. Mr. Voisey, the assistant medical officer on duty, being summoned, found the man suffering from excruciating pain in the left side, urgent dyspnoea, blanched countenance, body bedewed with a cold and clammy perspiration; pulse small, quick (140 per minute), and easily compressible; his facial expression was indicative of great suffering, and his general appearance gave the impression that extensive internal hemorrhage had occurred. On examining the seat of pain, a slight swelling could now be perceived, characterized by expansile pulsation and dullness on percussion; but there was total absence of anything approaching the nature of a bruit. Slight pressure over the tumor gave great pain; the area of dullness was much increased, its boundaries being as follows; above, seventh intercostal space; below, crest of ilium; in front, a line drawn vertically from the anterior fold of the axilla to the crest of the ilium; and behind, the vertebral column. Over the rest of the abdomen the percussion note was normal, and remained so in whatever position the patient was placed. One grain of opium was ordered to be taken every three hours. The following morning (June 23d), after a moderately good night, his general condition seemed slightly improved, and on examination the area of dullness had not further increased, but the expansile pulsation of the tumor was much more distinct, though still, on auscultation, no bruit could be detected. The radial pulse was almost imperceptible; the pain had abated in severity. The patient continued in this state until 9:45 the same evening, when the breathing suddenly became gasping, and he died a few minutes afterwards from syncope.

Necropsy, seventy-two hours after death.—Surface of body very much blanched; lips pale. On opening the abdomen, the peritoneal cavity was found to contain a large quantity of blood-clot, by far the larger mass having gravitated into the cavity of the pelvis. In the left lumbar region was a large fluctuating tumor, which had displaced the intestines and left kidney forwards to the right. Extending upwards, it had encroached upon the left lung, and crossing the middle line, a pouch as large as a hen's egg was situated in front of the right kidney. On cutting the peritoneum over the tumor, the left kidney was found pushed forward by a mass of coagulated blood effused between its posterior surface and the sheath of the psoas muscle; after removing this clot, the psoas was found abnormally large and misshapen, and on incising it a large quantity of

clotted blood, macerated muscular tissue, and laminated fibrin escaped. A horizontal incision was then made through the tumor, prolonged across the middle line to the small tumor first mentioned as situated in front of the right kidney; both the cavities communicated with the aorta by means of large openings. There was no trace of the posterior surface of the aorta, and the limiting sac of the aneurism behind was formed solely by the bodies of the first and second lumbar vertebræ, which were much eroded, and the intervertebral disc standing out between them unaltered. There was an irregular rent in the peritoneum at the junction of the sac of the aneurism of the left side, with the healthy part of the aorta through which the fatal gush into the peritoneal cavity must have occurred. Aorta studded with atheromatous patches; other organs healthy, but excessively anæmic.

The Physiology of Blood Pressure.

The *Lancet* says that some experiments carried on during the past year by Professor H. Newell Martin, and described by him in a paper published in the Transactions of the Medical and Chirurgical Faculty of the State of Maryland, appear to be of great value in determining the effect of variations of blood-pressure upon the pulse-rate. When it was shown that by increasing the pressure in the arteries the pulse was slowed, it was assumed that the greater force to be overcome by the ventricle entailed a longer systole, and that the result was the direct effect of the pressure upon the muscular tissue of the heart. The discovery that there is in the medulla oblongata a cardio-inhibitory centre which is stimulated by increased blood-pressure, and also a cardio-accelerator centre stimulated by lessened blood-pressure, and that the effects described by Marey were to be traced to the action of these centres, rendered necessary further investigations to determine whether variations in blood-pressure have any direct influence upon the pulse-rate. The results obtained by such trustworthy observers as Heidenhain, Ludwig, v. Bezold, and others, have been found to vary so greatly that no reliance whatever can be placed upon them. Professor Martin has, by eliminating apparently every source of error, arrived at constant and decided results, which also serve to explain the contradictory statements of previous observers. His mode of procedure is as follows: The animal—a dog—having been tracheotomized, placed under curari, morphia, or chloroform, the common carotid arteries are tied, and canulas placed in their central end. Artificial respiration is then established, the front and sides of the chest removed, and the two subclavian arteries are tied below the origin of their first branch. One limb of a curved metal canula is then introduced into the aorta, and thus all circulation through the systemic arteries except the coronaries is blocked. The two venæ cavæ and the vena azygos are tied, and a large tube in communication with a flask of defibrinated blood is introduced into the superior cava on the cardiac side of the ligature. The carotids are then opened, and all the blood in the heart and lungs is washed out by the defibrinated blood. While this is being done a thermometer is placed in the left subclavian artery. The animal

is then transferred to a warm, moist chamber; the superior cava is connected with a Mariotte's flask, from which defibrinated blood under a known and easily regulated pressure enters the vein and the right auricle. The blood flowing from the aorta is collected in another similar flask. The venous pressure can be altered by raising or lowering the Mariotte's flask, and the arterial pressure can be increased or diminished by elevating or lowering the exit point of the tube connected with the aorta. All being ready, arterial pressure, as measured in the carotid, was varied between the limits of 40 mm. and 210 mm. of mercury, and tracings taken of it and of the pulse-rate. Although this was done repeatedly, and both suddenly and gradually, it was found to in no way influence the pulse-rate, which gradually and uniformly fell. If the venous and arterial pressure were coincidentally greatly increased, the character and rapidity of the pulse were profoundly altered. If while the arterial pressure was kept constant, the pressure in the vein was altered by raising or lowering of the Mariotte's flask, in the same way the pulse-rate underwent no change. The experiments, which were often repeated, curari, morphia, and chloroform being used in turn, so as to exclude any effect of these agents, show that alterations in the blood-pressure, either arterial or venous, do not directly affect the pulse-rate.

In a further series of observations Professor Martin maintained the blood-pressure in both vein and arteries at a constant level, but varied the temperature of the defibrinated blood supplied to the heart, and he found that the pulse-rate rose with every increase in the temperature of the blood, and fell as it cooled. The fact that the pulse quickens with rise of temperature has, of course, long been familiar, but it was explicable upon two theories. The hot blood might act directly upon the tissue of the heart, or, paralyzing the cardio-inhibitory centre in the medulla oblongata, influence the heart indirectly. Martin has now shown that a dog's heart, completely liberated from all possible influence of nerve-centres outside itself, slows its rate of beat from minute to minute, as the temperature of the blood sent through the coronary artery falls, and quickens its beat as the temperature rises; and it has yet to be proved that the increased frequency of the pulse in the febrile state is in any way dependent on paralysis or excitation of the cardio-inhibitory or cardio-excitor centres in the medulla. In attempting to find the extremes of temperature compatible with cardiac life, it was found that a dog's heart would beat regularly and slowly at 26°C., and regularly, but rapidly and feebly, at 41°C.

Professor Martin shows how his investigations explain the results of other observers laboring at the same problem. For example, v. Bezold, in some experiments on curarized rabbits, with all extrinsic cardiac nerves divided, increased the blood-pressure in one of three ways. He either raised the hind part of the animal, and so pressed blood from the belly to the heart; or, after opening the chest, he clamped the aorta just beyond the origin of the left subclavian artery; or he injected into one carotid calf's blood carefully warmed to 38°C. By each of these methods not only was the blood-pressure increased, but the

temperature of the blood in the heart was raised, and so the increased frequency of the pulse was produced. In the first experiment, abdominal blood, nearly 20°C. hotter than that in the external jugular vein, was forced back to the heart in excess. In the second experiment, when the aorta was clamped, the blood forced into the aorta returned from the head and fore limbs much faster than before, and a larger amount of blood flowed through the lungs in a given time, and as only the same amount of cool air was pumped into the lungs by artificial respiration, the blood was much less cooled; or, in other words, the blood then reached the coronary vessels hotter, and so raised the pulse-rate. It has been shown that one effect of curari on the dog is to lower the temperature of the venous blood 3°C. Assuming that the effect is the same in the rabbit, the calf's blood at 38°C. introduced into the carotid artery in the third experiment, was 3°C. hotter than that in the veins, so that here again the means taken to raise the blood-pressure also raised the blood-temperature. Professor Martin has been successful in eliminating this source of error, and has apparently reduced a complex problem to its simplest conditions, and has succeeded in obtaining results of great value and importance.

Histogenesis of Carcinoma.

In the *Philadelphia Medical Times*, for January 13, 1883, Dr. Reed presents an article entitled *Histogenesis of Carcinoma*, this having been the subject of his inaugural thesis. The paper is divided into two parts; first, the development of epithelium studied in the healing of experimentally produced ulcers; second, the study of the minute anatomy of cancers. Seven experiments are detailed, and the conclusion reached that the epithelial covering of ulcers only arises from pre-existing epithelium. Then follows the last part of the paper, which is taken up with views of authors, some attempts at skin grafting, the application of his experiments and his personal observations of microscopical sections of carcinomata, especially scirrhi of the breast. At all points he convinces himself that just as the epithelium of healing ulcers arises from some pre-existent epithelium, so do all cancers originate from an epithelial source. The paper concludes with the points in favor of the exclusive epithelial origin of cancers. The following are quoted:

1. Primary true cancers are found only in locations where there is pre-existing epithelium, and no cancer has been proved to have originated heterotopically.

2. The cicatrization of cancers explains young connective tissue in filtration and connective tissue cells, and white-blood corpuscles are never seen inside the alveoli.

3. The intactness of the endothelial ensheathments of the alveoli.

4. The results of his experiments showing that the epithelial covering in healing ulcers is exclusively derived from the border epithelium—this fact, by analogy, forming strong testimony in favor of the epithelial origin of cancer.

The subject-matter and experiments of this paper are very interesting and a credit to their author; but the manner in which he states many points, the summary method of disposing of the

evidence of men like Stricker, Virchow, Woodward, etc., and the way in which he brings forward his seven experiments and few months' study of carcinomatous sections as sufficient evidence to overthrow all views differing from those adhered to in the paper, are arrogant in the extreme, and detract much from an otherwise very creditable production.

REVIEWS AND BOOK NOTICES.

NOTES ON CURRENT MEDICAL LITERATURE.

—An "Anti-Vivisection Society" has been organized in this city, and we have been favored with a large amount of the literature it distributes, such as "Dr. Bell Taylor on Vivisection," "The Torture Chamber of Science," by Baron von Weber, "Why Agitate against Vivisection?" by Dr. Walker, "Have Pity," by J. C. Scholl, "The Uselessness of Vivisection," by Lawson Tait, etc. We do not know a dozen vivisectors in the State of Pennsylvania, and every one of those we do know carries on his researches with the least possible pain to the animal. There seems here, therefore, a tremendous preparation to attack a very small-sized offense; but, after all, it is no offense, as every one of these investigators is prompted by the best and worthiest motives that can influence the human heart—the pursuit of truth and the relief of human suffering. That intelligent men and women should band together to attack such laborers, is a striking instance how prejudice, the desire of publicity, and the influence of mistaken sentiment, will blind people of good education and impulses to the motives and pursuits of others.

—The criticisms of Prof. Esmarch on the case of President Garfield have met with a caustic rejoinder from the pen of Dr. William Hunt, of this city. It constitutes his annual address before the Philadelphia Academy of Surgery, and makes a reprint of 22 pages.

—One of our most active alienists is Dr. C. H. Hughes, of St. Louis, editor of the *Alienist and Neurologist*, a position which he fills with distinguished capacity. Two reprints by him are before us which will certainly attract the attention of students of that branch. The one is on "The Rights of the Insane," the other sets forth some new experiences of an opium eater during the withdrawal of the drug, and while at a distance from his physician. A third paper on "The Therapeutic Value of Cephalic and Spinal Electrizations," is a suggestive contribution to special therapeutics.

—The Illinois State Board of Health is doing a good work in widely disseminating a series of "Preventable-Disease Circulars." Those before us refer to typhoid fever, scarlet fever, and diphtheria. They are written in plain terms, contain clear and well-chosen directions, and cannot fail to benefit the public. Copies of them may be obtained by applying to the Secretary of the State Board of Health, Springfield, Illinois.

—In a reprint before us, Drs. S. Weir Mitchell and Edward T. Reichert make a partial study of the poison of *Heloderma suspectum* (Cope), otherwise known as "the Gila monster." It is a species of lizard, which appears to be, at certain times, at least, capable of producing severe toxic symptoms.

—In the *Zeitschrift für Museologie und Antiquitätenkunde*, Dresden, the editor, Dr. Graesse, is writing a series of articles on the symbolism of plants and flowers, in the course of which he gives much attention to the ancient medical "doctrine of signatures," and to other curious vagaries of antique medical notions.

BOOK NOTICES.

Anatomical Technology as Applied to the Domestic Cat: An Introduction to Human, Veterinary, and Comparative Anatomy. With illustrations. By Burt G. Wilder, M. D., etc., and Simon H. Gage, B. S., New York. A. S. Barnes & Co., 8vo., pp. 575.

The authors of this work present a treatise on anatomy which may justly be said to be alone of its kind among the productions of the American press. As may be judged from the title, it is intended to be an introduction to the *science* of anatomy, whether that be of man or of the lower animals, of vertebrates or invertebrates.

Approaching the subject with this comprehensive view of its treatment, the authors begin by setting forth certain methods of work, which, if observed, will vastly facilitate the learner's progress. Thus the metric system is explained, and the new terminology adopted by the writers is fully set forth. We say *adopted*, but, perhaps, it would be more correct to say *invented*, for although Dr. Barclay, many years ago, laid the groundwork of the matter, his suggestions have been so amplified and critically supported by Dr. Wilder, it is nothing more than fair to the latter to give him the credit for this valuable terminology. We have examined it carefully, and though one who

has familiarized himself with the received nomenclature will feel some repulsion in first approaching these novel words, yet the more it is studied, the more obvious do its merits become.

Hints on the best method of taking notes are followed by a chapter on the instruments and material for study. A very valuable chapter is that on the preparation and preservation of anatomical specimens. The use of alcohol is recommended, and the methods of employing it are carefully specified. Preservation by injections is also described, and the most useful practical directions for carrying it out are noted.

These preliminaries understood, the student is then taken systematically through the component parts of the animal frame. Chapters are devoted to the bones, the muscles, the viscera, the vascular system, the nervous system, and the encephalon.

The demonstrations are made upon the domestic cat, this animal being for many reasons that which is best calculated to be made the subject of study by one desirous of mastering anatomy in the full meaning of the word. Many illustrations are, however, drawn from the anatomy of other animals, and the veterinarian, the physician, and the naturalist, will alike find the volume one from which they can derive very great aid in their respective pursuits. We believe it will greatly advance the study of anatomy in this country.

Transactions of the Medical Society of the State of Pennsylvania. Volume XIV., page 467.

At the period of the meeting of this State Society we gave sufficiently full abstracts of the principal papers read to enable us to dispense with more on the subject. Suffice it to say that they are here presented in a handsomer form than in previous volumes, and that they impress the reader as carefully prepared and instructive. The County Reports fill about a hundred pages, and cannot be said to present as much of interest as in some previous years. It is to be regretted that this feature is not made more prominent.

Manual of Gynecology. By D. Berry Hart, M. D., and A. H. Barbour, M. D. Vol. II.

It will be remembered from our report of Vol. I. of this work (REPORTER, cur. vol., p. 158) that it is issued by William Wood & Co., as part of their Library of Standard Medical Authors. It is neatly printed, and is illustrated with a lithograph and over two hundred wood-cuts. Few members of the series surpass it in character, the authors being writers of very good repute in the Edinburgh School of Medicine.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	\$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium, - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

With January 1st, 1883, the COMPENDIUM OF MEDICAL SCIENCE, formerly published half yearly, has been commenced as a *quarterly*, to be issued on the 1st of January, April, July, and October.

It is especially adapted to be taken with the REPORTER, as few or none of the articles in it appear in our weekly journal.

The price of subscription remains the same, \$2.50 per year. But as a special inducement to subscribers to the REPORTER to take the COMPENDIUM also, we offer the two journals at the very low price of

SIX DOLLARS,

when paid for *strictly in advance* and directly to this office.

THE RELATIONS OF MICRO-ORGANISMS TO DISEASE.

W. T. Belfield, M. D., in a lecture before the Alumni Association, College of Physicians and Surgeons, New York, (*New York Medical Journal*, February 24 and March 3, 1883), says that he had chosen the subject simply because of its intrinsic interest and importance, and also because there existed in the mind of the medical public in this country a divided opinion regarding it, which seemed to him not to be warranted by the facts.

The study of micro-organisms is an excessively difficult one, owing to the need for the proper facilities in pursuing investigations in the laboratory, and the amount of time and expense required to carry on the work intelligently. There is a tendency for the profession to treat the subject as a trivial or fanciful one, and in general to ignore it. Bacteria have been observed as early as 1675, but they suddenly acquired an interest to pathologists in 1861, when Pasteur endeavored to show a genetic relation between plants and diseases.

Cohn's definition of bacteria, formulated in 1875, is still applicable, "Cells devoid of chlorophyll, spherical, oblong, or cylindrical, which reproduce themselves extensively by transverse division, and live either isolated or in families." Nutrition and assimilation were carried on by a process of osmosis.

Their simplicity of organization explains their extensive distribution throughout nature.

Certain errors in manipulation and misinterpretations of facts, which were so liable to take place even with the greatest care and most improved facilities for investigation; would account for the serious mistake made by Pasteur and others in saying that bacteria were capable of spontaneous generation; there is no reason to suppose that bacteria, like all other organisms, do not always proceed from pre-existing similar beings. The nomenclature, unfortunately, is much confused, each investigator naming according to his fancy. The French school, following Pasteur, makes use of the terms vibrios, monads, torulacæ, etc. Cohn's classification, according to Dr.

Belfield, is probably the best; however, it needs some improvements. This nomenclature distinguishes the bacteria by form as micrococci, microbacteria, bacilli, spirilla.

The doctor thus defines bacterium: A mass of matter of definite shape and size, possessing or not possessing motion, of a certain chemical composition, having the power of growth and reproduction. No mass of matter can be said to be bacteria unless it possesses these qualities.

Even the mycologist cannot determine beyond doubt that a given object is one of the bacteria, except by cultivation outside of the body, thus demonstrating its reproductive power; but just here comes the practical hitch—many objects may come in contact with the particle under examination which might also contain bacteria. The doctor referred to cases showing how mistakes which had been made in the dissection had led to very erroneous conclusions.

The only means by which an organism in a culture can be shown to be the progeny of that first transplanted, is that it must be observed to proceed from it by continuity of structure: in order so to do we must directly observe it under the microscope. To do so, we must use a solid vehicle for the nutrition and cultivation of the organism. A solution of gelatine, beef extract, peptone, etc., is sterilized, and spread upon a disinfected slide, and allowed to dry; a heated needle is then dipped into the material containing the bacteria, and drawn lightly over the substance upon the slide, by which a scratch is made, to the edges of which the bacteria adhere; the slides are now to be placed in the incubator.

By this method we are able to know that the bacterium in the hundredth culture, for example, is structurally the same as the organism taken from the animal which had suffered from the disease in which the original bacterium was found.

Billroth asserts the presence of bacteria in perfectly healthy animals. Koch, Pasteur, and Ehrlich, have never so detected them.

Abnormal composition of the blood seemed to favor the development of some bacteria, after they

had gained entrance to the body, as abscesses in diabetic patients are swarming with micrococci.

The important and practical question is, to what extent the bacteria which are found in the tissues during certain morbid conditions are to be considered as the cause of the conditions with which they are associated.

In order to set this question at rest it must be demonstrated by culture of the bacteria found to exist in the diseased person, and the induction of the same disease in healthy animals by inoculation with a reproduction of the bacteria. The question to-day rests about as follows:

Diseases, the demonstration of the bacterial origin of which has been completed through inoculation with isolated bacteria by competent observers: anthrax.

Diseases, the bacterial origin of which has been affirmed after inoculation with isolated bacteria by one competent observer: tuberculosis.

Diseases which were always characterized by the presence of bacteria in the tissues, but which had not been induced by inoculation with isolated bacteria: pyæmia, diphtheria, erysipelas, etc.

Diseases in which after death bacteria have been found in the tissues: variola, scarlatina, typhoid fever, etc.

Diseases in which the presence of bacteria before and after death have been asserted: syphilis, typhus fever, intermittent fever, measles, etc.

THE MEDICO-LEGAL SOCIETY, OF NEW YORK CITY.

The Medico-Legal Society, of New York city, an association which has done much in recent years to suggest improvements in the laws of New York treating of the management of the insane, and kindred topics, has been considering for some time the important subject of coroners' inquests. A committee was appointed some time since, and has just made a careful report, which has been adopted by the Society.

This report is in the shape of a bill, which the Society has decided to urge upon the Legislature for its passage at the present session.

The bill is interesting as showing the views of a

large number of the medical profession in regard to the proper procedure in case of sudden death, either by violence or where there is no attending physician.

The most radical feature of the bill is legislating coroners' juries out of existence, and replacing them with medical examiners.

It has been found that coroners' juries, being composed, generally, of men little acquainted with the causes or signs of sudden death, have, with but few exceptions, rendered verdicts which were without weight or importance. It has also been often found that the juries have contained many persons who were annoyed at being summoned at all, and felt it a grievance to be obliged to give up their private business to attend to such a disagreeable matter as deciding upon the causes or circumstances of sudden death. As a result of this latter fact, juries have generally been composed of men without education or experience, frequently of the class known as professional jury-servers; and as a natural consequence, the public have almost ceased to be interested in or to place confidence in the verdicts of coroners' juries.

The power which a coroner has of setting aside the verdict, has contributed also to the general dissatisfaction with the whole method of procedure.

In place of the coroner's jury, the bill provides that there shall be in each Assembly District one examiner, except in the city of Brooklyn, where there shall be two, and in New York, where there shall be four. The medical examiners shall be able and learned in the science of medical jurisprudence, and shall have been for at least five years in the active practice of their profession. They shall also be selected without regard to political or partisan considerations.

The term of office is to be seven years, and the compensation, fees, except in Brooklyn and New York, where there is a salary affixed to the office of \$5,000.

The duties of the medical examiners are to make an examination of the body of any person reported to have been slain, or suddenly died, or dangerously wounded, or to have died from crimi-

nal violence, or suddenly when in apparent health, or when unattended by a physician.

In case a crime has been committed which caused or contributed to the death, careful reports shall be made to the nearest coroner and the district attorney of the county, of all the circumstances tending to show the condition of the body and the manner of death.

Upon such a report being made to the coroner, he shall at once hold an inquest, and shall have power to issue subpoenas and commit to prison, or hold to bail, as may be proper. The general duties of a court having powers of preliminary inquiry are attached to the office of coroner.

The medical examiners are given the power to call in the help of chemists for the proper examination of the body, or of substances supposed to have caused death.

The medical examiners are also to take charge of money or personal property found on the bodies of deceased persons, and to deliver the same to the persons entitled to their custody or possession.

This bill will shortly come before the Legislature of New York, and has in its favor the support of a large and influential society, composed about equally of physicians and lawyers.

DR. FORBES ACQUITTED.

It gives us pleasure to record the acquittal of Dr. Forbes, Demonstrator of Anatomy in the Jefferson Medical College, of the charge of complicity with the grave-robbers who were last fall tried and convicted.

It would have been a great hardship had Dr. Forbes been convicted.

He was doing what has been done, and is done, and always will be done; he desired to procure enough material to enable his students to properly prosecute their anatomical studies, and he went about it in the ordinary, customary manner. That he was in collusion with a lot of men to steal bodies from cemeteries, is ridiculous on its face, when we consider Dr. Forbes' standing and reputation.

We heartily congratulate Dr. Forbes and the

science of anatomy, and we cannot but condemn those who refused him the support to which he was so justly entitled.

NOTES AND COMMENTS.

Leucoplakia Buccalis.

The *Chicago Medical Journal* quotes the following from *L'Union Méd.*:

"This disease, also called psoriasis of the tongue and buccal mucous membrane, is a chronic squamous affection of the dorsum of the tongue and the lips, characterized by white elevated spots and superficial induration of the mucous membrane. It is mostly found in persons having been affected by syphilis of the mouth, or in persons addicted to the use of tobacco. But sometimes it is found in persons neither syphilitic nor smokers, and then there are seen round erythematous spots, looking very red, but later blackish, and which undergo desquamation. If the disease has continued for several years, there are large grayish spots, which become black and are thrown off in lamellæ 3 cm. long. Then there is cicatrization, with the new formation of epithelial cells, and the surface of the tongue becomes broken and fissured in different directions. At last the tongue shows several elevated points, which look like the papillæ of the tongue of a cat. These points are confluent, and they form at last the true epithelioma."

Recurrence of Scarlatina within Eight Months.

F. P. Kinnicutt, M. D., in *N. Y. Med. Record*, March 3, 1883, says that he attended a male child aged five, in a typical attack of scarlet fever, having a favorable termination; eight months afterwards he was again called to the same child, and the diagnosis of scarlatina was again made: slight albuminuria made its appearance in the third week and still persists; patient has suffered with a number of boils on various parts of the body.

Dr. Kinnicutt remarks that a second infection of scarlet fever occurring within the short period of eight months, in which all the characteristic symptoms are manifested with as much prominence as in the primary attack, is sufficiently rare to be worthy of record. The doctor has only been able to find six other recorded cases of a similar nature; the shortest and longest period of recurrence were respectively thirty-six days and nine months.

The above case conflicts with the terse and generally accepted statements of the various textbooks, "one attack protects from a second."

Chloroform vs. Ether.

After stating the fact that several deaths have been lately reported from chloroform, the *Louisville Med. News* says:

"Death occurred suddenly in all these cases from paralysis of the heart, and the most skillful and persistent efforts to revive the patient were made without avail. In none of these cases were any evidences of heart disease found by auscultation and percussion, and no lesion was suspected. The lesson of these recent accidents with chloroform is that in the most experienced and careful hands death may occur from this agent; that chloroform is particularly dangerous when exhibited to subjects having weak hearts; that recent experiences confirm the belief already prevailing in America in the superiority of ether over chloroform as a safe anæsthetic."

An Unusual Case of Polydipsia.

A woman aged 40, of hysterical temperament, had been troubled for three years with gurgling, plashing and whirring sounds of confined liquid issuing from the region of her stomach, with such violent action as to irresistibly jerk and agitate her whole body. All treatment had proved useless, when she came under the notice of Dr. D. D. Marr, of Chesterton, Ind., who reports the case in the *Chicago Med. Jour.*, February, 1883. She would drink from one to two gallons of water per day, and pass urine in large quantities; sp. gr. 1.008, no sugar. Subnitrate of bismuth, in drachm doses, three or four times daily, was the only remedy that gave any relief. She subsequently became pregnant, after a favorable termination of which her condition greatly improved.

Hot Pack in Puerperal Eclampsia.

Dr. Brens expresses the opinion in the *Arch. f. Gyn.*, that for the cure of puerperal eclampsia either in the puerperium or the last months of pregnancy, active diaphoresis alone, induced by a hot bath, 40 to 45°C, followed by the pack, is all sufficient. The bath must not be prolonged over one-half hour, and two to three hours suffices for the envelopment in the pack. This method properly carried out, according to Brens, will also cause œdema and albuminuria to disappear without interruption of pregnancy.

A New Reaction of the Urine in Infectious Diseases.

The *Med. News*, February 10, 1883, says that at a recent meeting of the Gesellschaft der Charité-Aerzte, in Berlin, Ehrlich described a new reaction of the urine. When a solution of sulphanilic

acid (*sulphanilsäure*) and ammonia is added to the urine from cases of tuberculosis, typhoid, or other infectious fever, a bright-red color is produced. The urine from cases of ordinary inflammatory or febrile diseases does not give this reaction. The details are promised.—*Berliner klin. Woch.*, January 1, 1883.

Syphilitic Gumma in the Liver.

A case is reported in *France Méd.* The patient was a girl, aged 15. The liver was much enlarged, appetite diminished, colicky pains, and diarrhoea. After improving on a diet of milk, the symptoms returned, with vomiting, and after repeated aspirations of albuminous fluid she died. It is probable that the case was one of hereditary syphilis.

Brassicon.

From the *Pharm. Zeit. f. Russl.*, 1882, 783, we learn that a remedy bearing this name has a great reputation for headache in the province of Kiew, Russia. The formula is as follows:

Oil of peppermint	30 grs.
Oil of mustard, volatile.	6 gtt.
Camphor	10 grs.
Ether	60 gtt.
Alcohol (90%)	180 gtt.
Tincture of peppermint (or melissa) enough to impart color.	

The Treatment of Obstinate Neuralgia.

The *Medical Record*, January 15, 1883, says that M. Verneuil, in a communication to the Surgical Society of Paris (*Le Prog. Méd.*, No. 49, 1882), referring to the surgical treatment of obstinate neuralgia, said that all therapeutic resources should be exhausted before surgical interference was undertaken. He recalled a case which was cured by hyoscyamin, after resection of all the ends of nerves, and even amputation, had failed.

Negative Effect of Vaccination on Fœtus.

In the *Maryland Medical Journal*, January 15, 1883, Dr. Powell reports the case of a lady in the eighth month of pregnancy, whom he vaccinated successfully. Since her confinement her child has been vaccinated and has had a typical crust and scar, showing the absence of any protective influence from the mother's vaccination.

The Weight of the Brain in Mental Diseases.

France Méd. says that Dr. Bra has found that in mental diseases the brain weighs a little more than usual, and the circumference of the cranium is a little larger.

Chlorinated Oil in Scabies.

A new remedy for this affection is made by passing chlorine into olive oil. A compress of cotton saturated with this oil is to be applied night and morning. It is said to be equally efficacious in other parasitic skin affections.

A Palatable Cough Mixture.

The most elegant and palatable cough mixture ever prescribed by Dr. J. Milner Fothergill, is, he says, the following:

R. Syr. Scillæ,	3 j.
Acid. hydrobromic. dil.,	3 ss.
Spirits chloroform,	3 ss.
Aquæ,	3 j.

Late Tying of the Umbilical Cord.

Dr. Edward Alcorn gives a resume of the experience of various writers on this subject, which proves that the children whose cords are left uncut until after the placenta has been expelled, thrive much better than those in whom it is cut before.

Spina Bifida Cured by Injections of Iodine.

Dr. E. Muirhead Little reports a case of spina bifida, where recovery followed aspiration and the injection of an iodo-glycerine solution.

SPECIAL REPORT.

THERAPEUTIC PROGRESS.

Arsenic in Diabetes.

Dr. Longeville, in the *Jour. de Thérapeutique*, December 10, 1882, states that in his experiments he found that arsenic was a great obstacle to the formation of sugar, as shown by administering it to dogs prior to puncturing the fourth ventricle. Clinical results, as far as observed in two diabetic patients upon whom the experiment was tried, corroborated this conclusion; for a few days' dosing with Fowler's solution, progressively increased from ten to thirty drops per diem, diminished the quantity of sugar by more than one-half. The quantity of the urine passed while under the influence of the arsenic was diminished in like proportion.

Quassine.

In the *Gaz. des Hop.*, Dr. Delmis says that the active principle of quassia amara (quassine) is a bitter tonic with aperient and stomachic properties, and is a valuable tonic in general debility, atonic dyspepsia, anorexia, chlorosis, spasmodic vomiting, and prolonged and difficult convalescence.

The dose is from $\frac{1}{3}$ to $\frac{2}{3}$ of a grain, given before each of the principal meals.

Caffein for Hypodermic Use.

Dr. Tanret, in *Schmidt's Jahrbücher*, No. 7, 1882, says that the ordinary preparations of caffein are unsuitable for hypodermic use, because they are so slightly soluble in water. He finds that caffein unites readily with benzoate, cinnamomate, or salicylate of soda, forming a double salt, readily soluble in water, which containing sixty-one per cent. of caffein, has been injected subcutaneously without causing the slightest irritation.

Phenic Acid and Iodine in Typhoid Fever.

The *Medical Record* says that Dr. Klamann (*Allgem. Med. Central-Zeitung*, No. 81, 1882), claims excellent results in the treatment of typhoid fever by carbolic acid and iodine. To avoid carbolic-acid poisoning he gives very small doses, as in the following formula: Tinct. iodi., gtt. viiiss.; acid. carbol. c. glycerin, gtt. x.; alcohol, dilut., $\mathfrak{z}$ iiss. From five to ten drops of this mixture are taken in coffee or tea every hour or two. When diarrhoea is troublesome the remedy is administered in tincture of rhatany. The treatment should be begun early in the disease, in order to obtain the most favorable results.

A similar plan of treatment is recommended by Dr. Rothe (*Memorabilien*, vol. xxvii.), who reports a number of cases, in some of which the initial symptoms were very grave, but all of which resulted favorably. The formula employed by him is as follows: Acid. carbol. et alcohol, $\mathfrak{a}\mathfrak{a}$ $\mathfrak{M}$ viiss. to xv. (according to the age of the patient, the intensity of the fever, etc.); tinct. iodi., gtt. x. to xv.; aq. menth. pip., $\mathfrak{z}$ iij.; tinct. aconiti, $\mathfrak{M}$ xv. to xxx.; syr. aurant. cort., $\mathfrak{z}$ iv. Of this mixture the dose is a tablespoonful every hour; for children under ten years of age, a teaspoonful. Owing to the aconite in this mixture, however, it is difficult to determine how much of the good effect is to be attributed to the carbolic acid and iodine.

Jequiriti in the Treatment of Granulation of the Conjunctiva.

The *Medical News* quotes from the *Gaz. Med. de Paris*, December 23, 1882, that at the meeting of the Société de Chirurgie, held December 13, M. Terrier read a report on a memoir of M. José Cardoso, of Rio Janeiro, on the employment of this drug. The jequiriti is a leguminose plant; an infusion made of the seeds and employed as a lotion to the conjunctiva in cases of granulations, sets up an acute inflammation, and may, in large doses, even cause severe accidents. M. de Wecker has employed the preparation with satisfactory results, while in the only case in which M. Terrier

employed it an intense purulent conjunctivitis was set up, which was cured without the granulations undergoing the least improvement. So while in certain cases it may be used with success, it should always be employed with caution. M. Desprès maintained that the only justifiable treatment of this disease was excision of the granulations when chronic, while, when inflammatory, they may be cured by cauterization with sulphate of zinc or nitrate of silver.

The Mullein Plant in Pulmonary Consumption.

There are five mulleins, but the old Irish remedy is the great mullein, or *verbascum thapsus*. It is a hardy biennial, with a thick stalk, from eighteen inches to four feet high, and with very peculiar large woolly and mucilaginous leaves, and a long flower-spike with ugly yellow and nearly sessile flowers. The leaves are best gathered in late summer or autumn, shortly before the plant flowers. In former times, it appears to have been rather highly thought of, particularly as a remedy for diarrhoea; and Dioscorides, Culpepper, and Gerarde favorably allude to it.

Dr. F. J. B. Quinlan, of Dublin, decided to try its effects in pulmonary consumption, and his results are published in the *British Medical Journal*, January 27, 1883.

The old Irish method of administering the mullein, is to place an ounce of the dried leaves, or a corresponding quantity of the fresh ones, in a pint of milk; to boil for ten minutes, and then to strain. This strained fluid is given warm to the patient, with or without a little sugar. It is administered twice a day; and the taste of the mixture is bland, mucilaginous, comforting to the præcordia, and not disagreeable. I resolved to try this method, and also the watery infusion; and, moreover, the natural expressed juice fortified with glycerine.

Some phthisical sufferers were now admitted from time to time into St. Vincent's Hospital, in all stages, from an early one to the most advanced. On each admission, the case was carefully examined; the history, symptoms, and physical signs were exactly noted; and the patient was weighed on a stage balance of great accuracy. The patient was put as much as possible on the mullein treatment only. For obvious reasons, no cod-liver oil, koumiss, or other weight-producer was given; the patients got the diet suitable to such sufferers; and, if the special symptoms became troublesome, received appropriate treatment. As much as possible, however, they were left to the mullein—a proceeding which was entirely satisfactory to themselves. In addi-

tion to the admission-weighing, they were carefully weighed every week, and care was taken that this should be done as nearly as possible on the same day and hour, with the same clothes, and, in fact, as much as could be under the same conditions.

The mullein was used in seven cases, and the following are his remarks: "I have set down the above cases simply in the order in which they occurred, and with no view of supporting any preconceived idea. These cases, although too few to justify any general conclusion, appear to establish some useful facts. The mullein plant boiled in milk is liked by the patients; in watery infusion it is disagreeable, and the succus is still more so. The hot milk decoction causes a comfortable (what our Gallic neighbors call *pectorale*) sensation, and when once patients take it, they experience a physiological want, and when the supply was once or twice interrupted, complained much in consequence. That it eases phthisical cough there can be no doubt; in fact, some of the patients scarcely took their cough mixtures at all—an unmixed boon to phthisical sufferers with delicate stomachs. Its power of checking phthisical looseness of the bowels was very marked, and experiment proved that this was not merely due to the well-known astringent properties of boiled milk. It also gave great relief to the dyspnoea. For phthisical night-sweats it is utterly useless; but these can be completely checked by the hypodermic use of from one-eightieth to one-fiftieth of a grain of the atropia sulphate; the smaller dose, if it will answer, being preferable, as the larger causes dryness of the pharynx, and interferes with ocular accommodation. In advanced cases, it does not prevent loss of weight, nor am I aware of anything that will, except koumiss. Dr. Carrick, in his interesting work on the koumiss treatment of Southern Russia (page 213) says: 'I have seen a consumptive invalid gain largely in weight, while the disease was making rapid progress in her lungs, and the evening temperature rarely fell below 101° Fahr. Until then I considered that an increase of weight in phthisis pulmonalis was a proof of the arrest of the malady.' If koumiss possesses this power, mullein clearly does not; but unfortunately, as real koumiss can be made from the milk of the mare only, and as it does not bear travelling, the consumptive invalid must go at least to Samara or Southern Russia. In pretubercular and early cases of pulmonary consumption, mullein appears to have a distinct weight-increasing power; and I have observed this in several private cases also.

Having no weighings of these latter, however, makes this statement merely an expression of opinion. In early cases, the mullein milk appears to act very much in the same manner as cod-liver oil; and when we consider that it is at once cheap and palatable, it is certainly worth a trial. I will continue the research by careful weighings of early cases; and will further endeavor to ascertain whether the addition of mullein to the cultivating solution prevents the propagation of the phthisical bacillus."

Treatment of Cough and Expectoration.

Dr. Rossbach, desiring to place our therapeutics of these diseases on a rational instead of the present empirical basis, has experimented with the remedies usually in vogue. Through a wide opening in the trachea, he observed directly the effects of medicines taken internally or applied locally, having beside him an undrugged animal for comparison. His conclusions are found in *Berlin Klin. Woch.*, 1882, Nos. 19, 20. He directed his attention first to alkalis, using locally solution of carbonate of sodium and liquor ammonii, and internally carbonate of sodium and chloride of ammonium. The *Brit. Med. Jour.*, January 27, 1883, thus condenses his results. Thirty grains of carbonate of sodium, or fifteen grains of chloride of ammonium, injected into a cat's femoral vein, caused increasing pallor and grayish white appearance of the mucous membrane, and ultimately a complete cessation of mucous secretion. While the mucous membrane of the normal animal, after being dried with blotting paper, became moist again in two minutes, that of the drugged animal showed no trace of mucus till ten minutes, and if this small quantity were dried off, no more appeared.

What the cause of this cessation is, Dr. Rossbach does not say; but it cannot be the anæmia, as the secretion continues unaltered in much higher grades of anæmia from nerve stimulation. The diminution of the blood-supply and mucous secretion of the bronchial membrane, evidently tend towards an actual cure of the pathological conditions usually involved. Solutions of one to two per cent. of sodic carbonate applied locally seemed to produce no effect; but even very weak dilutions of liquor ammoniæ caused a marked injection of the mucous membrane, with distinctly increased secretion. The local application of a weak solution of acetic acid produced the same effect as liquor ammoniæ; and Dr. Rossbach, both from his experiments and observations, is strongly opposed to the use of this drug in throat affections.

The astringent remedies observed were tannin, alum, and nitrate of silver. Local application of the former two caused the surface to become pale, the opaque epithelium, however, preventing the condition of the blood-vessels from being observed. The secretion was completely abolished, the surface being dry and shining. These facts were still more markedly true of solution of nitrate of silver, which produced a sharply limited patch of chalky white color, over which the mucous secretion was entirely absent. Dr. Rossbach is inclined to believe that the vessels are really contracted, and from a long experience he strongly recommends the local application of solution of nitrate of silver in all cases of inflammation of the mucous membrane, more especially when accompanied with pain, feeling of dryness, etc.

The local effect of oil of turpentine on the mucous membrane was somewhat perplexing, as, when sprayed directly on a spot, it caused dryness of the mucous membrane, while a two-per cent. solution dropped on a spot caused an increased mucous secretion, notwithstanding there was a diminution of vascularity. Dr. Rossbach strongly recommends oil of turpentine, both internally and locally, in cases of chronic bronchial catarrh, more especially with putrid expectoration. He believes that it has not only an antiseptic, but also a refrigerant and narcotic effect.

The action of apomorphia, emetine, and pilocarpine, was observed both in large and in small doses. With all three, but more especially with the last, there was a very great increase of the mucous secretion in the larynx, trachea, and bronchi, the mucous glands becoming so large as to cause projections on the surface. This effect Dr. Rossbach proves to result from a direct action of the drug on the gland itself, the circulation of the blood being quite unaffected. The subsidiary effects of pilocarpine render it unsuitable as a practical expectorant; but apomorphia Dr. Rossbach considers to be the prototype of all expectorants, giving in his hands most excellent results. He administers it as hydrochlorate of apomorphia in doses of one-fifteenth to one-seventh of a grain thrice daily, with a little dilute hydrochloric acid, the mixture being kept in a dark bottle and containing no sugar.

Lastly, Dr. Rossbach gives the results of his experiments with atropia and morphia. Atropia produces extreme dryness of the tracheal mucous membrane, accompanied by a gradually increasing hyperæmia. Its effect in deadening the irritability of the membrane is, he finds, very uncertain; while, on the other hand, the effect of mor-

phia, both in diminishing the secretion and lessening irritability, is constant. Another advantage possessed by morphia is that the diminution of the secretion is never so great as to be followed by inflammation, which, he asserts, is frequently the case with atropia. A combination of morphia and apomorphia he has found extremely useful in cases of difficult expectoration, while a combination of morphia and atropia has given excellent results in cases of chronic catarrh, emphysema, and phthisis. Electrical stimulation of the superior laryngeal nerve causes distinct contraction of the blood-vessels, justifying, therefore, Ziemssen's recommendation of percutaneous electrization of the larynx in cases of obstinate chronic inflammation.

Bromide of Potassium in Chordee.

In the *Bull. de Therap.*, December 30, 1882, Dr. Cambillard states in a recent *thèse* that he has seen this painful affection successfully treated at the Midi by means of injections of bromide of potassium, and supplies the following formula: Water 150 parts by weight, glycerine 10, bromide of potassium 6, and Resseau's laudanum 2 parts. Four of these injections should be employed in the twenty-four hours, the last just before bedtime. Each injection should be retained one or two minutes. The erections are usually speedily calmed, and sometimes completely suppressed. They are nowise painful, causing only in some persons a slight burning sensation. They act by anæsthetizing the urethral mucous membrane.

The Frequent Repetition of Doses.

Dr. A. A. Smith, Professor of Mat. Med. in Bellevue Hosp. Med. Coll., contributes a valuable paper on this subject to the *New York Med. Jour.*, February 10, 1883, from which we take the following:

Chlorate of Potash.—Grain doses every half hour in scarlet fever, diphtheria, tonsillitis, etc., will produce the same results as larger doses, without the danger of the evil effects resulting from the accumulation of the drug in the system, as sometimes happens when it is administered in the ordinary way; viz., dangerous inflammation of the kidneys. It is better, when giving *croton chloral* for neuralgia to administer a grain every half hour, than in larger doses. A solution, of which a teaspoonful represents one grain, will have scarcely any bad taste. Another advantage is, that being so largely diluted, it will be harmless to the mucous membrane of the stomach.

Two grains of the *salicylate of sodium* every hour or half hour in a teaspoonful of water will cure the most obstinate cases of *urticaria*, except those

of a chronic nature, and where it has been caused by full doses of *balsam of copaiba*, single drop doses of the same drug every half hour will sometimes control it.

Fowler's solution, or the liquor potassii arsenitis, half a drop given every half-hour for six or eight doses will often relieve the vomiting which occurs after a debauch. It will also relieve the morning vomiting of drunkards, and is of decided benefit in the sympathetic nausea and vomiting of pregnancy.

Five to ten minim doses of the fluid extract of *laborandi* every hour or half hour will produce copious perspiration, without causing any unpleasant effects upon the heart, especially if combined with digitalis.

In *supposed croup*, which is usually false croup of a reflex origin, a teaspoonful of a solution of one one-hundredth of a grain of sulphate of atropine in a tumbler of water, every hour or half hour, will give relief.
